Bscore

B score normalization

Description

Correction of plate and spatial effects of data stored in slot `assayData` of a `cellHTS` object using the B score method (without variance adjustment of the residuals). Using this method, a two-way median polish is fitted, on a per-plate basis, to account for row and column effects.

Usage

```
Bscore(object, save.model = FALSE)
```

Arguments

`object` a `cellHTS` object that has already been configured. See details.
`save.model` a logical value specifying whether the per-plate models should be stored in slots `rowcol.effects` and `overall.effects`. See details.

Details

This function is usually not called directly by the user, but from within the `normalizePlates` function. The normalization is performed in a per-plate fashion using the B score method, for each replicate and channel. In the B score method, the residual r_{ijp} of the measurement for row i and column j on the p -th plate is obtained by fitting a [two-way median polish](#), in order to account for both row and column effects within the plate:

$$r_{ijp} = y_{ijp} - \hat{y}_{ijp} = y_{ijp} - (\hat{\mu}_p + \hat{R}_{ip} + \hat{C}_{jp})$$

y_{ijp} is the measurement value in row i and column j of plate p (taken from slot `assayData` - only sample wells are considered), and \hat{y}_{ijp} is the corresponding fitted value. This is defined as the sum between the estimated average of the plate ($\hat{\mu}_p$), the estimated systematic offset for row i (\hat{R}_{ip}), and the systematic offset for column j (\hat{C}_{jp}).

NOTE: In the original B score method, as presented by Malo et al., a further step is performed: for each plate p , each of the obtained residual values r_{ijp} 's are divided by the median absolute deviation of the residuals in plate p (MAD_p), resulting in:

$$\frac{r_{ijp}}{MAD_p}$$

The intention of such a further adjustment is to compensate for plate-to-plate variability in dynamic range. In the `Bscore` function, this step is not automatically performed, but can be done if B score normalization is called using the function `normalizePlates` with arguments `method="Bscore"` and `varianceAdjust="byPlate"`. See the latter function for more details.

If `save.model=TRUE`, the models row and column offsets and overall offsets are stored in the slots `rowcol.effects` and `overall.effects` of object.

Value

An object of class `cellHTS` with B-score normalized data stored in slot `assayData`.

Furthermore, if `save.model=TRUE`, the row and column effects and the overall effects are stored in slots `rowcol.effects` and `overall.effects`, respectively. The latter slots are arrays with the same dimension as `Data(object)`, except the `overall.effects` slot, which has dimensions `nr Plates x nr Samples x nr Channels`.

After calling this function, the processing status of the `cellHTS` object is updated in the slot `state` to `object@state["normalized"]=TRUE`.

Data

Access and replace the assayData slot of a cellHTS object

Description

This generic function accesses and replaces the data stored in slot `assayData` of an object of `cellHTS` class.

Usage

```
Data(object)  
Data(object) <- value
```

Arguments

<code>object</code>	Object derived from class <code>cellHTS</code> .
<code>value</code>	a 3D array of dimensions <code>dim(object)[1]</code> (this corresponds to the total number of features: number of wells per plate x number of plates) x <code>dim(object)[2]</code> (this corresponds to the number of samples or replicates) x number of channels.

Value

`Data` returns a 3D array containing the contents of slot `assayData`. This array has dimensions number of features (product between the number of wells per plates and the number of plates) x number of samples (or replicates) x number of channels. Depending on the preprocessing status of the `cellHTS` object, this array corresponds to the raw data, or to normalized data or to scored data.

See class `cellHTS` for details.

`cellHTS`

ROC-class

Class that contain data that can be plotted as a ROC curve.

Description

Container for data that represent a receiver-operator-characteristic curve, and that were generated from the data of the annotated positive and negative controls in a scored `cellHTS` object.

Creating Objects

```
new("ROC")
```

§4methodROCcellHTS(object, positives, negatives) with `object` being an `cellHTS` instance.

Slots

name: a character of length 1 with the name of the experiment from which the ROC object derives.

assayType: a character of length 1 with the type of screening assay. Possible values are: "one-way assay" and "two-way assay".

TP: a vector of integers of length 1000.

FP: a vector of integers of length 1000.

posNames: a character vector with the name of the positive controls.

negNames: a character vector with the name of the negative controls.

Methods

show Print a summary of the object.

plot Plot the ROC curve corresponding to the object.

lines Line plot of the ROC object.

Author(s)

Ligia Bras (ligia@ebi.ac.uk), Wolfgang Huber (huber@ebi.ac.uk)

See Also

[ROC](#)

Examples

```
showClass("ROC")
showMethods(class="ROC")

## Not run:
data(KcViabSmall)
x <- normalizePlates(KcViabSmall, scale="multiplicative", log=FALSE, method="median",
x <- scoreReplicates(x, sign="-", method="zscore")
x <- summarizeReplicates(x, summary="mean")
y <- ROC(x)
plot(y)
lines(y, col="green")
```

```

    show(y)

## End(Not run)

```

 ROC

Creates an object of class "ROC" which can be plotted as a ROC curve

Description

The function `ROC` construct an object of S4 class `ROC`, which represents a receiver-operator-characteristic curve, from the data of the annotated positive and negative controls in a scored `cellHTS` object.

Usage

```

## S4 method for signature 'cellHTS':
ROC(object, positives, negatives)
## S4 method for signature 'ROC, missing':
plot(x, col="darkblue", type="l", main = "ROC curve", ...)
## S4 method for signature 'ROC':
lines(x, ...)

```

Arguments

<code>object</code>	a <code>cellHTS</code> object which replicate data have already been scored and summarized (see details).
<code>positives</code>	a list or vector of regular expressions specifying the name of the positive control(s). See the details for the argument <code>posControls</code> of <code>writeReport</code> function. The default is <code>"^pos\$"</code> .
<code>negatives</code>	a vector of regular expressions specifying the name of the negative control(s). See the details for the argument <code>negControls</code> of <code>writeReport</code> function. The default is <code>"^neg\$"</code> .
<code>x</code>	a <code>ROC</code> object obtained using function <code>ROC</code> .
<code>col</code>	the graphical parameter for color; see <code>par</code> for details.
<code>type</code>	the graphical parameter giving the type of plot desired; see <code>par</code> for details.
<code>main</code>	the graphical parameter giving the desired title of plot; see <code>par</code> for details.
<code>...</code>	other graphical parameters as in <code>par</code> may be also passed as arguments.

Details

The `cellHTS` object `object` must be already scored (`state(object) ["scored"] = TRUE`), and selection proceeds from large to small values of this single per-probe score. Furthermore, `object` is expected to contain positive and negative controls annotated in the column `controlStatus` of the `featureData` slot - which can be accessed via `wellAnno(object)`. The arguments `positives` and `negatives` should be given as regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively. By default, if `positives` is not given, `pos` will be taken as the name for the wells containing positive controls. Similarly, if `negatives` is missing, by default `neg` will be considered as the name used to annotate the negative controls. The content of `posControls` and `negControls` are passed to `regexpr` for pattern matching within the well annotation (see examples for `summarizeChannels`). If the assay is a two-way experiment, `positives` should be a list with components `act` and `inh`, specifying the name of the activators, and inhibitors, respectively. In this case, the ROC curve is constructed based on the absolute values of `Data(object)`.

Value

An S4 object of class `ROC`. There are methods `show`, `plot` and `lines`.

Author(s)

Ligia P. Bras (ligia@ebi.ac.uk)

Examples

```
data(KcViabSmall)
x <- normalizePlates(KcViabSmall, scale="multiplicative", log=FALSE, method="median",
x <- scoreReplicates(x, sign="-", method="zscore")
x <- summarizeReplicates(x, summary="mean")
y <- ROC(x)
plot(y)
lines(y, col="green")
show(y)
```

annotate

Annotates the reagents (probes) of a cellHTS object

Description

Annotate the reagents (probes) of a `cellHTS` object. In RNAi-screens, there is often a 1:1 correspondence between reagents and intended target genes, hence in this software package the term gene ID is used as a synonym.

Usage

```
## S4 method for signature 'cellHTS':
annotate(object, geneIDFile, path)
```

Arguments

<code>object</code>	a <code>cellHTS</code> object.
<code>geneIDFile</code>	the name of the file with the gene IDs (see details). This argument is just passed on to the <code>read.table</code> function, so any of the valid argument types for <code>read.table</code> are valid here, too. Must contain one row for each well in each plate.
<code>path</code>	a character of length 1 indicating the path in which to find the gene annotation file (optional).

Details

`geneIDFile` This file is expected to be a tab-delimited file with at least three columns, and column names `Plate`, `Well` and `GeneID`. The contents of `Plate` are expected to be integer. Further columns are allowed.

Value

An S4 object of class `cellHTS`, which is obtained by copying `object` and updating the following slots:

<code>featureData</code>	the contents of the annotation file are stored here.
<code>state</code>	the processing status of the <code>cellHTS</code> object is updated to <code>state["annotated"] = TRUE</code> .

x <- readPlateList("Platelist.txt", path=datadir, name="KcViabSmall")
x <- configure(x, "Description.txt", "Plateconf.txt", "Screenlog.txt", path=datadir)
x <- annotate(x, "GeneIDs_Dm_HFASubset_1.1.txt", path=datadir)
```

batch

Access and replace the batch slot of a cellHTS object

Description

This method accesses and replaces the data stored in the slot `batch` of a `cellHTS` object.

Usage

```
batch(object)
batch(object) <- value
```

Arguments

<code>object</code>	object of class <code>cellHTS</code> .
<code>value</code>	a 3D array of integer values giving the batch number for each plate, sample and channel. Its dimensions should be equal to <code>dim(object)[1]</code> (this corresponds to the total number of features: number of wells per plate x number of plates) x <code>dim(object)[2]</code> (this corresponds to the number of samples or replicates) x number of channels.

Value

Data returns a 3D array containing the contents of slot `batch`. This array has dimensions number of features (product between the number of wells per plates and the number of plates) x number of samples (or replicates) x number of channels of the current `cellHTS` object.

See class `cellHTS` for details.

cellHTS-class	<i>A class for data from cell-based high-throughput assays performed in plate format.</i>
---------------	---

Description

Container for data and experimental meta-data from cell-based high-throughput assays performed in plate format. Typical applications are RNA interference or small molecular compound screens. The class extends the `NChannelSet` class. Data are from experiments where the same set of reagents (probes) were used. The class can represent data from multi-channel assays.

The data can be thought of as being organised in a two- or three-dimensional array as follows:

- The first dimension corresponds to reagents (e.g. siRNAs, chemical compounds) that were used in the assays. For example, if the screen used 100 plates of 384 wells (24 columns, 16 rows), then the first dimension has size 38,400, and the `cellHTS` object keeps track of plate ID, row, and column associated with each element. For historic reasons, and because we are using infrastructure that was developed for microarray experiments, the following terms are used synonymously for the elements of the first dimension: reagents, features, probes, genes.
- The second dimension corresponds to assays, including replicates and different experimental conditions (cell type, treatment, genetic background). A potentially confusing terminology is that the data structure that annotates the second dimension is called `phenoData`. This is because we are using infrastructure (the `NChannelSet` class) that uses this unfortunate term for this purpose.
- The (optional) third dimension corresponds to different channels (e.g. different luminescence reporters)

Objects from the Class

Objects can be created by calls of the form `new("cellHTS", assayData, phenoData, ...)`. See the examples below.

Slots

plateList: a `data.frame` containing what was read from input measurement data files plus a column `status` of type character containing the string "OK" if the data import appeared to have gone well, and the respective error or warning message otherwise.

intensityFiles: a list, where each component contains a copy of the imported input data files. Its length corresponds to the number of rows of `plateList`.

state: a logical vector of length 4 representing the processing status of the object. It must have the names "configured", "normalized", "scored" and "annotated".

plateConf: a `data.frame` containing what was read from the *configuration file* for the experiment (except the first two header rows). It contains at least three columns named `Plate`, `Well` and `Content`. Columns `Plate` and `Well` are allowed to contain regular expressions.

screenLog: a `data.frame` containing what was read from the *screen log file* for the experiment, in case it exists. Contains at least three columns, and column names `Plate`, `Well`, and `Flag`. Additional columns are `Sample` (when there are replicates or more than one sample or condition) and `Channel` (when there are multiple channels).

screenDesc: a character containing what was read from the *description file* of the experiment.

batch: a 3D-array with the first two dimensions corresponding to the dimension of each matrix in `assayData` slot and the third dimension corresponding to the number of channels in `assayData` slot (Features x Samples x Channels). Should contain integer values giving the batch number (1, 2, ...) for each plate, sample and channel.

rowcol.effects: a 3D array of size Features (i.e. plate size x number of plates) x Samples x Channels containing estimated row and column plate spatial offsets.

overall.effects: a 3D array of size Features x Samples x Channels containing estimated plate overall offsets.

assayData: Object of class `AssayData`, usually an environment containing matrices of identical size. Each matrix represents a single channel. Columns in each matrix correspond to samples (or replicate), rows to features (probes). Once created, `cellHTS` manages coordination of samples and channels.

phenoData: Object of class `AnnotatedDataFrame`. Please see the documentation of the `phenoData` slot of `NChannelSet` for more details.

It contains information about the screens, and it must have the following columns in its `data` component: `replicate` and `assay`, where `replicate` is expected to be a vector of integers giving the replicate number, while `assay` is expected to be a vector of characters giving the name of the biological assay. Both of these vectors should have the same length as the number of Samples.

Once created, `cellHTS` coordinates selection and subsetting of channels in `phenoData`.

featureData: Object of class `AnnotatedDataFrame`, containing information about the reagents: plate, well, column, the well annotation (sample, control, etc.), etc. For a `cellHTS` object, this slot must contain in its `data` component at least three mandatory columns named `plate`, `well` and `controlStatus`. Column `plate` is expected to be a numeric vector giving the plate number (e.g. 1, 2, ...), `well` should be a vector of characters (alphanumeric characters) giving the well ID within the plate (e.g. A01, B01, H12, etc.). Column `controlStatus` should be a factor specifying the annotation for each well with possible levels: *empty*, *other*, *neg*, *sample*, and *pos*. Other levels besides *pos* and *neg* may be employed for controls.

experimentData: Object of class `MIAME` containing descriptions of the experiment.

annotation: A "character" of length 1, which can be used to specify the name of an annotation package that goes with the reagents used for this experiment.

.__classVersion__: Object of class `Versions`, containing automatically created information about the class definition, Biobase package version, and other information about the user system at the time the instance was created. See `classVersion` and `updateObject` for examples of use.

Extends

Class `NChannelSet`, directly.

Methods

Methods with class-specific functionality:

name(object) `signature(object="cellHTS")`. Obtains the name of the assay stored in the object. This corresponds to the contents of column `assay` of the `phenoData` slot of the `cellHTS` object.

name(object) <- value `signature(object = "cellHTS", value = "character")` assign the character of length one (`value`) to the elements in column `assay` of the slot `phenoData` of object.

pdim(object) signature(object = "cellHTS"). Obtain the plate dimension for the data stored in object.

nbatch(object) signature(object = "cellHTS"). Obtain the total number of batches for the data stored in object.

compare2cellHTS(x, y) signature(x = "cellHTS", y = "cellHTS"). Compares two `cellHTS` objects, `x` and `y`, returning `TRUE` if they are from the same experiment (i.e. if they derive from the same initial `cellHTS` object), or `FALSE` otherwise.

Methods with functionality derived from class `NChannelSet`: `channel`, `channelNames`, `selectChannels`, `object[features, samples]`, `sampleNames`

Methods with functionality derived from `eSet`: `annotation`, `assayData`, `assayData<-`, `classVersion`, `classVersion<-`, `dim`, `dims`, `experimentData`, `featureData`, `phenoData`, `phenoData<-`, `pubMedIds`, `sampleNames`, `sampleNames<-`, `storageMode`, `varMetadata`, `isCurrent`, `isVersioned`.

Additional methods:

initialize used internally for creating objects

show invoked automatically when the object is displayed to the screen. It prints a summary of the object.

state Access the `state` slot of a `cellHTS` instance.

annotate Annotate the `cellHTS` object using the *screen annotation file*.

configure Configure the `cellHTS` object using the *screen description file*, the *screen configuration file* and the *screen log file*.

writeTab Write the contents of `assayData` slot of a `cellHTS` object to a tab-delimited file.

ROC Construct an object of S4 class `ROC`, which represents a receiver-operator-characteristic curve, from the data of the annotated positive and negative controls in a scored `cellHTS` object.

meanSdPlot(x) signature(x = "cellHTS") plots row standard deviations across samples versus row means across samples for data stored in slot `assayData` of a `cellHTS` object. If there are multiple channels, row standard deviations and row means are calculated across samples for each channel separately. Only wells containing "sample" are considered. See `meanSdPlot` for more details about this function.

cellHTS2 Package Overview

Description

cellHTS2 Package Overview

Details

This package provides data structures and algorithms for cell-based high-throughput assays performed in plate format. Typical applications are RNA interference or small molecular compound screens. The most important data class is `cellHTS`, which extends the `NChannelSet` class.

Full help on methods and associated functions is available from within class help pages.

Data sets: `KcViab`, `KcViabSmall`, `oldKcViabSmall`, `dualCh`, `bdgpbiofarmt`.

Introductory information is available from vignettes, type `openVignette()`.

Class-specific methods: `annotate`, `batch`, `batch<-`, `compare2cellHTS`, `configure`, `Data`, `Data<-`, `geneAnno`, `intensityFiles`, `name`, `name<-`, `nbatch`, `pdim`, `plate`, `plateConf`, `plateEffects`, `plateList`, `position`, `screenDesc`, `screenLog`, `state`, `well`, `wellAnno`, `writeTab`, `ROC`.

Generic functions: `show`, `initialize`, `validObject`.

Other functions: `oneRowPerId`, `write.tabdel`, `readPlateList`, `readHTAnalystData`, `normalizePlates`, `Bscore`, `spatialNormalization`, `plotSpatialEffects`, `summarizeChannels`, `scoreReplicates`, `summarizeReplicates`, `imageScreen`, `configurationAsScreenPlot`, `getEnVisionRawData`, `getEnVisionCrosstalkCorrectedData`, `getTopTable`, `getMeasureRepAggr`, `getDynamicRange`, `getZfactor`, `writeReport`, `convertOldCellHTS`, `scores2calls`, and `templateDescriptionFile`.

A full listing of documented topics is available in HTML view by typing `help.start()` and selecting the `cellHTS2` package from the Packages menu or via `library(help="cellHTS2")`.

See Also

Below, we present a list of ‘high level’ functions in the cellHTS2 package together with a brief description of what they do.

Data import:

`readPlateList` read a collection of plate reader data files.

`readHTAnalystData` read input files from a HTAnalyser plate reader containing data for a set of plate replicates.

`getEnVisionRawData` this function can be used as an import function when calling `readPlateList` to read plate result files obtained from EnVision Plate Reader.

`getEnVisionCrosstalkCorrectedData` this function can be used as an import function when calling `readPlateList` to read plate result files obtained from EnVision Plate Reader.

Screen configuration and annotation:

`annotate` annotates the reagents (e.g. siRNAs, molecular compounds) of a `cellHTS` object.

`configure` annotates the plates and the plate result files of a `cellHTS` object.

Accessors:

`batch` accesses and replaces the `batch` slot of a `cellHTS` object.

`Data` accesses and replaces the `assayData` slot of a `cellHTS` object. It returns a 3D array with dimensions number of features (product between the number of wells per plates and the number of plates) x number of samples (or replicates) x number of channels.

`geneAnno` returns the reagent IDs used in the screen (i.e. the contents of `fData(object)[, "GeneID"]`).

`intensityFiles` returns a list, where each component contains a copy of the imported input data files.

`name` obtains the name(s) of the assay, or multiple assays, stored in the `object`. This corresponds to the contents of column `assay` of the `phenoData` slot of the `cellHTS` object.

`pdim` obtains the plate dimensions (number of rows and columns) for the data stored in `object`.

`plate` plate identifier for each feature (well).

`plateConf` returns a `data.frame` that contains what was read from the plate configuration input file (except the first two header rows) during the screen configuration step.

`plateList` returns a `data.frame` containing what was read from the plate list file, plus a column `status` of type `character` that contains the string "OK" if the data import appeared to have gone well, and the respective error or warning message otherwise.

`plateEffects` accesses the slots `rowcol.effects` and `overall.effects`.

`position` gives the well number for each feature (well) within each plate.

`screenDesc` returns an object of class `character` that contains what was read from the screen description input file during the configuration of the `cellHTS` object.

`screenLog` returns a `data.frame` containing what was read from the screen log input file during the screen configuration step.

`state` This generic function accesses the state of an object derived from the `cellHTS` class.

`well` gives the alphanumeric identifier (e.g. A01, A02, ...) for each well and plate.

`wellAnno` accesses the plate annotation stored in `fData(object)[, "controlStatus"]`.

Data preprocessing:

All the following methods work on the data stored in the slot `assayData` of a `cellHTS` object.

`normalizePlates` per-plate data transformation, normalization and variance adjustment.

`Bscore` correction of plate and spatial effects using the B score method (without variance adjustment of the residuals).

`spatialNormalization` correction of spatial effects by fitting a polynomial surface within each plate using local regression (`loess` or `robust local fit`). Uses a second degree polynomial (local quadratic fit). Only wells containing "sample" are considered to fit the models.

`summarizeChannels` combines intensities from a dual-channel assay by applying the function defined in `fun`.

`scoreReplicates` transform per-replicate values into scores.

`summarizeReplicates` summarizes between normalized and scored replicate values, obtaining a single value for each probe.

`scores2calls` applies a sigmoidal transformation to the z-score values stored in a `cellHTS` object mapping them to the range [0,1].

Miscellaneous:

`compare2cellHTS` compares two `cellHTS` objects to see whether they derive from the same initial `cellHTS` object.

`convertOldCellHTS` converts an old S3 class `cellHTS` object obtained using `cellHTS` package to new S4 class `cellHTS` object(s) to use with package `cellHTS2`.

`convertWellCoordinates` converts between different ways of specifying well coordinates within a plate. For example, wells can be identified by an alphanumeric character (e.g. "B02" or c("B", "02")) or by an integer value (e.g. 26).

`ROC` creates an object of class `ROC` from a scored `cellHTS` object which can be plotted as a ROC curve.

`getTopTable` generates the hit list from a scored `cellHTS` object and write it to a tab-delimited file.

`getMeasureRepAgreement` calculates the agreement between plate replicates using raw data or normalized data stored in a `cellHTS` object.

`getDynamicRange` calculates per-plate dynamic range of data stored in a `cellHTS` object.

`getZfactor` calculates per-experiment Z'-factor of data stored in a `cellHTS` object. The Z'-factor is a measure that quantifies the separation between the distribution of positive and negative controls.

`plotSpatialEffects` this function plots the per-plate row and column effects estimated by the B score method or by the spatial normalization.

`imageScreen` creates an image plot that gives an overview of the whole set of score values stored in a scored `cellHTS` object.

`writeReport` creates a directory with HTML pages of linked tables and plots documenting the contents of the preprocessing of a `cellHTS` object.

`oneRowPerId` rearranges dataframe entries such that there is exactly one row per ID.

`nbatch` gives the total number of batches in a `cellHTS` object.

`templateDescriptionFile` creates a template description file for an RNAi experiment with default entries compliant with MIAME class and with additional entries specific for a `cellHTS` object.

`writeTab` this function is a wrapper for the function `write.table` to write the contents of `assayData` slot of a `cellHTS` object to a tab-delimited file. If the object is already annotated, the probe information (`fData(object)@GeneID`) is also added.

`write.tabdel` a wrapper for the function `write.table` used to write data to a tab-delimited file.

`meanSdPlot` method for `meanSdPlot` (from the `vsr` package) to construct the standard deviation versus mean plot of data stored in a `cellHTS` object.

configurationAsScreenPlot

Screen plot of the plate configuration of a cellHTS object

Description

Screen plot displaying the plate configuration of a `cellHTS` object.

Usage

```
configurationAsScreenPlot(x, verbose=interactive(), posControls, negControls)
```

Arguments

- | | |
|--------------------------|--|
| <code>x</code> | a configured <code>cellHTS</code> object (i.e. <code>state(x) ['configured']</code> must be <code>TRUE</code>). |
| <code>verbose</code> | a logical value, if <code>TRUE</code> , the function reports some of its intermediate progress. The default is <code>HYPERLINK(interactive()) (interactive())</code> . |
| <code>posControls</code> | a list or vector of regular expressions specifying the name of the positive controls. See details. |
| <code>negControls</code> | a vector of regular expressions specifying the name of the negative controls. See details. |

Details

This function calls the function `plotScreen` to create a screen plot showing the plate configuration (as defined by the plate configuration file used to configure the `cellHTS` object – see function `configure`) used for the RNAi experiment stored in `x`.

`posControls` and `negControls` should be given as vectors of regular expression patterns specifying the name(s) of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file (and accessed via `wellAnno(x)`).

By default, if `posControls` is not given, "pos" will be taken as the annotation name for the wells containing positive controls. Similarly, if `negControls` is missing, by default "neg" will be considered as the name used to annotate the negative controls. The content of `posControls` and `negControls` will be passed to `regexpr` for pattern matching within the well annotation given in column `controlStatus` of the `featureData` slot of the `cellHTS` object.

Value

Invisibly, a vector with the color map used to display the well annotation in the image plot.

Examples

```
data("KcViab")
configurationAsScreenPlot(KcViab)
```

configure

Configures the plates and plate result files

Description

Annotate the plates and the plate result files of a [cellHTS](#) object.

Usage

```
## S4 method for signature 'cellHTS':
configure(object, descripFile, confFile, logFile, path)
```

Arguments

<code>object</code>	a cellHTS object.
<code>descripFile</code>	the name of the screen description file (see details). This argument is just passed on to the readLines function, so any of the valid argument types for readLines are valid here, too.
<code>confFile</code>	the name of the configuration file (see details). This argument is just passed on to the read.table function, so any of the valid argument types for read.table are valid here, too. Must contain one row for each well and each batch.
<code>logFile</code>	optional; the name of the screen log file (see details). This argument is just passed on to the read.table function, so any of the valid argument types for read.table are valid here, too.
<code>path</code>	optional; a character of length one indicating the path in which to find the configuration files. It can be useful when the files are located in the same directory, and may be omitted otherwise.

Details

The configuration has three components:

confFile: This file specifies where the controls are. This file is expected to be a tab-delimited file with two first header rows giving the total number of wells and plates in the screen. The next rows should be in the form of a spreadsheet table with at least three columns named `Plate`, `Well` and `Content`. Columns `Plate` and `Well` are allowed to contain regular expressions. Data from wells that are configured as *empty* will be ignored and are set to `NA` in the data slot `xraw`. For an example, and for more details, please read the accompanying vignette.

logFile: This optional file allows to flag certain measurements as invalid. It is expected to be a tab-delimited file with at least three columns, and column names `Plate`, `Well`, and `Flag`. If there are multiple samples (replicates or conditions), a column called `Sample` should also be given. If there are multiple channels, a column called `Channel` must be given. Further columns are allowed.

descripFile: The screen description file contains general information about the screen.

Value

An S4 object of class `cellHTS`, which is obtained by copying `object` and updating the following slots:

<code>plateConf</code>	a data frame containing what was read from input file <code>confFile</code> (except the first two header rows).
<code>screenLog</code>	a data frame containing what was read from input file <code>logFile</code> .
<code>screenDesc</code>	object of class <code>character</code> containing what was read from input file <code>descripFile</code> .
<code>state</code>	the processing status of the <code>cellHTS</code> object is updated in to <code>state["configured"]=TRUE</code> .
<code>featureData</code>	the column <code>controlStatus</code> is updated taking into account the well annotation given by the plate configuration file.
<code>experimentData</code>	an object of class <code>MIAME</code> containing descriptions of the experiment, constructed from the screen description file.

```

convertOldCellHTS *Convert an old S3 class cellHTS object to the new S4 class cellHTS object*

Description

Convert an old S3 `cellHTS` object (from the `cellHTS` package) into one or several S4 `cellHTS` objects (from the `cellHTS2` package).

Usage

```
convertOldCellHTS(oldObject)
```

Arguments

`oldObject` an S3 class `cellHTS` object obtained using the package `cellHTS`.

Value

The function returns a list containing one or more `cellHTS` objects. The element `raw` contains the unnormalized data from `oldObject`. Depending on the state of `oldObject` (on whether it is normalized and scored), the other components of this list can be: `normalized`, an S4 `cellHTS` object containing the normalized data, and `scored`, an S4 class `cellHTS` object containing the scored data.

names(out)
out[["raw"]]
```

`convertWellCoordinates`*Converts different well identifiers*

Description

Converts between different ways of specifying well coordinates. For example, "B02" <-> c("B", "02") <-> 26.

Usage

```
convertWellCoordinates(x, pdim, type="384")
```

Arguments

<code>x</code>	either: a character vector with alphanumeric well identifiers (e.g. B03); or an <code>nx2</code> character matrix whose first column contains letters and whose second column contains numbers; or an integer vector with position identifiers for wells within a plate (e.g. 27).
<code>pdim</code>	a vector of length 2 with names <code>nrow</code> and <code>ncol</code> giving the number of rows and columns in a plate. E.g. <code>'c(nrow=16, ncol=24)'</code> for 384-well plates.
<code>type</code>	an alternative way of specifying <code>pdim</code> . Supported are the values "24" for <code>c(nrow=4, ncol=6)</code> , "96" for <code>c(nrow= 8, ncol=12)</code> "384" for <code>c(nrow=16, ncol=24)</code> .

Value

A list with elements: `letnum`, with the alphanumeric well identifiers; `let.num`, with the alphanumeric well identifiers giving as a pair `c(LETTER, 2-digits)`; `num`, with the integer position of the well within a plate.

```

getDynamicRange *Per-plate dynamic range of a cellHTS object*

Description

Calculates per-plate dynamic range of data stored in a `cellHTS` object.

Usage

```
getDynamicRange(x,
  verbose=interactive(),
  definition,
  posControls,
  negControls)
```

Arguments

<code>x</code>	a configured <code>cellHTS</code> object. See details.
<code>verbose</code>	a logical, if TRUE the function reports some of its intermediate progress. The default is the state of <code>HYPERLINK(interactive())(interactive())</code> .
<code>definition</code>	a character string with possible values "ratio" or "difference". See details.
<code>posControls</code>	(optional) a list or vector of regular expressions specifying the name of the positive controls. See details.
<code>negControls</code>	(optional) a vector of regular expressions specifying the name of the negative controls. See details.

Details

`x` should be an already configured `cellHTS` object (`state(x) ["configured"] = TRUE`), so that the information about the well annotation of the plates is available.

The per-plate dynamic ranges are calculated for the data stored in slot `assayData` of `x`. This can be raw data, normalized data or scored data.

If `definition="difference"`, the dynamic range is calculated as the absolute difference between the arithmetic average on positive and negative controls.

If `definition="ratio"`, the dynamic range is calculated as the ratio between the geometric mean on positive and negative controls.

NOTE: the argument `definition` should only be set to "ratio" if data are in positive scale!

If `definition` is missing it is determined based on the scale of the data. By default, if data are in positive scale, `definition` is set to "ratio", otherwise, it is set to "difference".

`posControls` and `negControls` should be given as a vector of regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file (and accessed via `wellAnno(x)`). The length of these vectors should be equal to the current number of channels in `x` (`dim(Data(x))[3]`). By default, if `posControls` is not given, `pos` will be taken as the name for the wells containing positive controls. Similarly, if `negControls` is missing, by default `neg` will be considered as the name used to annotated the negative controls. The content of `posControls` and `negControls` will be passed to `regexpr`

for pattern matching within the well annotation given in `wellAnno(x)` (see examples). If no controls are available for a given channel, use "" or NA for that channel. For example, `posControls = c("", "(?i)^diap$")` means that channel 1 has no positive controls, while `diap` is the positive control for channel 2.

The arguments `posControls` and `negControls` are particularly useful in multi-channel data since the controls might be reporter-specific, or after normalizing multi-channel data.

If there are different positive controls, the dynamic range is calculated between each of the positive controls and the negative controls.

In the case of a two-way assay, where two types of "positive" controls are used in the screen ("activators" and "inhibitors"), `posControls` should be defined as a list with two components (called `act` and `inh`), each of which should be vectors of regular expressions of the same length as the current number of reporters (as explained above). The dynamic range is calculated between each type of positive control (`activators` or `inhibitors`) and the negative controls.

Value

The function generates a list with the per-plate dynamic ranges in each channel and each replicate. The average dynamic range between replicates is also given. Each element of this list is an array of dimensions `nrPlates x (nrReplicates + 1) x nrChannels`, and is named by the positive controls. In the case of a two-way assay, these elements are called `activators` and `inhibitors`, while for a one-way assay, the elements have the same name of the positive controls. See Examples section.

```

getEnVisionRawData *Read a plate file obtain from EnVision Plate Reader*

Description

Import functions to read a plate file obtained from EnVision Plate Reader. These functions should be set as the import function of `readPlateList` through the argument `importFun` when reading plate result files obtained from EnVision plate reader.

Usage

```
getEnVisionRawData(f)
getEnVisionCrosstalkCorrectedData(f)
```

Arguments

`f` the name of the result plate file to read.

Details

These functions should not be called directly. Instead, they should be set as the import function of `readPlateList` through the argument `importFun` when reading plate result files obtained from an EnVision plate reader.

Value

These functions return a list with two components. The first component should be a 'data.frame' with the following slots: `well` (a character vector with the well identifier in the plate) and `val` (the intensity values measured at each well). The second component of this list should be a character vector containing a copy of the imported input data file (such as the output of `readLines`). It should be suitable to be used as input for `writeLines`.

## to get the cross talk corrected data:
onePlate2 <- getEnVisionCrosstalkCorrectedData(plateFile)
```

```
getMeasureRepAgreement
```

Measures of agreement between plate replicates from a cellHTS object

Description

Calculate the agreement between plate replicates using raw data or normalized data stored in a `cellHTS` object. This function calculates the repeatability standard deviation between replicate plates and the correlation coefficient between replicates. If there are more than 2 replicates, the minimum and maximum correlation between replicates is given. These measures are calculated only for `sample` wells.

Usage

```
getMeasureRepAgreement(x, corr.method = "spearman")
```

Arguments

`x` a configured `cellHTS` object. See details.

`corr.method` a character string indicating which correlation coefficient should be computed. Can be either "pearson", "kendall" or "spearman" (default). The correlation is calculated by calling the function `cor`.

Details

Given an already configured `cellHTS` object (`state(x)[["configured"]]=TRUE`), this function calculates the repeatability standard deviation between replicate plates and the correlation coefficient between plate replicates using only the `sample` wells. If there are more than 2 replicates, the minimum and maximum correlation value between pairs of replicates are given.

These measures are calculated using the data values stored in slot `assayData` of the `x`.

For a given plate p , the repeatability standard deviation is determined as the square root of the average of the squared standard deviations (sr) calculated for each sample well k by considering the measurement of all of the replicates:

$$RepStDev_p = \sqrt{\frac{\sum sr^2}{n_k}}$$

where n_k is the total number of sample probes for plate p .

Value

The function generates a list with elements:

"repStDev": matrix with the calculated repeatability standard deviation between plate replicates. It has dimensions `nrPlates` x `nrChannels`;

"corrCoef" (if the number of replicates equals 2): matrix with the correlation coefficients between plate replicates. It has dimensions: `nrPlates` x `nrChannels`;

"corrCoef.min" (if the number of replicates is greater than 2): matrix with the minimum value of the correlation coefficients between plate replicates. It has dimensions `nrPlates` x `nrChannels`;

"corrCoef.max" (if the number of replicates is greater than 2): matrix with the maximum value of the correlation coefficients between plate replicates. It has dimensions `nrPlates` x `nrChannels`.

[configure](#), [writeReport](#)

Examples

```
data(KcViabSmall)
repAgree <- getMeasureRepAgreement(KcViabSmall)
x <- normalizePlates(KcViabSmall, scale="multiplicative", log=FALSE, method="median",
repAgree <- getMeasureRepAgreement(x)
```

getTopTable

Generate the hit list from a scored cellHTS object

Description

Generate the hit list from a scored [cellHTS](#) object and write it to a tab-delimited file.

Usage

```
getTopTable(cellHTSlist, file="topTable.txt", verbose=interactive())
```

Arguments

`cellHTSlist` a list of [cellHTS](#) objects. See details.
`file` the name of the output file. Default is "topTable.txt".
`verbose` a logical value, if TRUE, the function reports its progress. Defaults to the state of `HYPERLINK(interactive()) (interactive())`.

Details

Argument `cellHTSlist` should be a list containing at least one component named "scored" which corresponds to a scored [cellHTS](#) object. Other possible components of `cellHTSlist` can be:

- "raw": a [cellHTS](#) object containing unprocessed data. I.e. `state(cellHTSlist[["raw"]])["norm`
- "normalized": a [cellHTS](#) object containing normalized data. I.e. `state(cellHTSlist[["normalize` and `state(cellHTSlist[["normalized"]])["scored"]=FALSE`.

All of the components of `cellHTSlist` should be [cellHTS](#) objects containing data from the same experiment, but in different preprocessing stages.

This function generates a `data.frame` that is written to `file`. This `data.frame` and the output file contain the list of scored probes ordered by decreasing score values. They have one row for each well and plate, and contain the following columns (depending on the components of `cellHTSlist`):

- `plate`: plate identifier for each well.
- `position`: gives the position of the well in the plate (ranges from 1 to the total number of wells in the plate).
- `well`: gives the alphanumeric identifier for the wells.
- `score`: content of slot `assayData` of the scored `cellHTS` object given in `cellHTSlist[["scored"]]`.
- `wellAnno`: well annotation as given by the plate configuration file.
- `finalWellAnno`: Gives the final well annotation for the scored values. It combines the information given in the plate configuration file with the values in `assayData` slot of the scored `cellHTS` object, in order to have into account the wells that have been flagged either by the screen log file, or manually by the user during the analysis. These flagged wells appear with the annotation *flagged*.
- `raw_ri_chj`: (if `cellHTSlist[["raw"]]` is given) contains the raw intensities for replicate `i` in channel `j` (content of slot `assayData` of the `cellHTS` object given in `cellHTSlist[["raw"]]`).
- `median_chj`: (if `cellHTSlist[["raw"]]` is given) corresponds to the median of raw measurements across replicates in channel `j`.
- `diff_chj`: (if `cellHTSlist[["raw"]]` is given and if there are two replicates or samples) gives the difference between replicate (sample) raw measurements in channel `j`.
- `average_chj`: (if `cellHTSlist[["raw"]]` is given and if there are more than 2 replicates or samples) corresponds to the average between replicate raw intensities for channel `j`.
- `raw/PlateMedian_ri_chj`: (if `cellHTSlist[["raw"]]` is given) this column gives the ratio between each raw measurement and the median intensity in each plate for replicate (or sample) `i` in channel `j`. The plate median is determined for the raw intensities using exclusively the wells annotated as `sample`.
- `normalized_ri_chj`: (if `cellHTSlist[["normalized"]]` is given) gives the normalized intensities for replicate (sample) `i` in channel `j`. This corresponds to the content of slot `assayData` of the `cellHTS` object given in `cellHTSlist[["normalized"]]`.

Additionally, if the `cellHTS` object given in `cellHTSlist[["scored"]]` is already annotated, the output `topTable` also contains the gene annotation stored in slot `featureData`.

Value

Generates the file with the hit list and outputs a `data.frame` with the same contents.

out <- getTopTable(cellHTSlist=list("raw"=KcViabSmall, "normalized"=xn, "scored"=xsc))
```

getZfactor

Per-experiment Z'-factor of a cellHTS object

Description

Calculates per-experiment Z'-factor of data stored in a `cellHTS` object. The Z'-factor is a measure that quantifies the separation between the distribution of positive and negative controls.

Usage

```
getZfactor(x,
  robust=TRUE,
  verbose=interactive(),
  posControls,
  negControls)
```

Arguments

<code>x</code>	a configured <code>cellHTS</code> object. See details.
<code>robust</code>	a logical, if <code>TRUE</code> the Z'-factor is calculated using the median and MAD instead of mean and standard deviation, respectively.
<code>verbose</code>	a logical, if <code>TRUE</code> the function reports some of its intermediate progress. The default is the state of <code>HYPERLINK(interactive()) (interactive())</code> .
<code>posControls</code>	(optional) a list or vector of regular expressions specifying the name of the positive controls. See details.
<code>negControls</code>	(optional) a vector of regular expressions specifying the name of the negative controls. See details.

Details

`x` should be an already configured `cellHTS` object (`state(x) ["configured"] = TRUE`), so that the information about the well annotation of the plates is available.

The per-experiment Z'-factor values are calculated for the data stored in slot `assayData` of `x`.

If `robust=TRUE` (default), the Z'-factor is calculated using robust estimates of location (median) and spread (`mad`).

`posControls` and `negControls` should be given as a vector of regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file (and accessed via `wellAnno(x)`). The length of these vectors should be equal to the current number of channels in `x` (`dim(Data(x)) [3]`). By default, if `posControls` is not given, `pos` will be taken as the name for the wells containing positive controls. Similarly, if `negControls` is missing, by default `neg` will be considered as the name used to annotated the

negative controls. The content of `posControls` and `negControls` will be passed to `regexpr` for pattern matching within the well annotation given in `wellAnno(x)` (see examples). If no controls are available for a given channel, use "" or NA for that channel. For example, `posControls = c("", "(?i)^diap$")` means that channel 1 has no positive controls, while `diap` is the positive control for channel 2.

The arguments `posControls` and `negControls` are particularly useful in multi-channel data since the controls might be reporter-specific, or after normalizing multi-channel data.

If there are different positive controls, the Z' -factor is calculated between each of the positive controls and the negative controls.

In the case of a two-way assay, where two types of "positive" controls are used in the screen ("activators" and "inhibitors"), `posControls` should be defined as a list with two components (called `act` and `inh`), each of which should be vectors of regular expressions of the same length as the current number of reporters (as explained above). The Z' -factor values are calculated between each type of positive control (`activators` or `inhibitors`) and the negative controls.

Value

The function generates a list with the per-experiment Z' -factor values in each channel and each replicate. Each element of this list is a matrix with dimensions `nrReplicates` x `nrChannels`, and is named by the positive controls. In the case of a two-way assay, these elements are called `activators` and `inhibitors`, while for a one-way assay, the elements have the same name of the positive controls. See examples section.

`imageScreen`*Experiment-wide quality control plot of a cellHTS object*

Description

Experiment-wide quality control plot of a scored `cellHTS` object.

Usage

```
imageScreen(object, ar = 3/5, zrange, map = FALSE, anno)
```

Arguments

<code>object</code>	a <code>cellHTS</code> object that has already been scored (i.e. <code>state(object) ['scored'] = TRUE</code>).
<code>ar</code>	the desired aspect ratio for the image plot (i.e. number of columns per number of rows)
<code>zrange</code>	the range of values to be mapped into the color scale. If missing, <code>zrange</code> will be set to the range of the score values stored in slot <code>assayData</code> of <code>object</code> .
<code>map</code>	a logical value that determines whether an image map should be created using tooltips to indicate the annotation at each position. It only makes sense to set it to <code>TRUE</code> when the function is called from <code>writeReport</code> function, so the default is <code>FALSE</code> .
<code>anno</code>	optional input giving the annotation information for the mapping. It should be a vector of the same size as the total number of featured in <code>object</code> . See details.

Details

This function creates an image plot that gives an overview of the whole set of score values stored in slot `assayData` of a scored `cellHTS` object. When the annotation mapping is performed, by default, `anno` is set to:

1. (if `object` is annotated) The content of column named `GeneSymbol` or named `GeneID` (if the former is not available) of the `featureData` slot of `object`;
2. The position within the plate, if `object` is not annotated.

imageScreen(x, zrange=c(-5,5))
```

intensityFiles	<i>Retrieve the contents of the input files used to generate a given cellHTS object.</i>
----------------	--

Description

These generic functions access different slots of an object derived from the `cellHTS` class, which contain the original content of the input files used to create the object.

Usage

```
intensityFiles(object)
plateList(object)
plateConf(object)
screenLog(object)
screenDesc(object)
```

Arguments

object an object of class `cellHTS`.

Value

`intensityFiles` returns a list, where each component contains a copy of the imported input data files.

`plateList` returns a data.frame containing what was read from the plate list file, plus a column status of type character that contains the string "OK" if the data import appeared to have gone well, and the respective error or warning message otherwise. See [readPlateList](#) for more details.

`plateConf` returns a data.frame that contains what was read from the plate configuration input file (except the first two header rows) during the screen configuration step. For more details see [configure](#).

`screenLog` returns a data.frame containing what was read from the screen log input file during the screen configuration step. See [configure](#) for more details.

`screenDesc` returns an object of class `character` that contains what was read from the screen description input file during the configuration of the `cellHTS` object. See [configure](#) for more details.

normalizePlates	<i>Per-plate data transformation, normalization and variance adjustment</i>
-----------------	---

Description

Plate-by-plate normalization of the raw data stored in slot `assayData` of a `cellHTS` object. Normalization is performed separately for each plate, replicate and channel. Log₂ data transformation can be performed and variance adjustment can be performed in different ways (none, per-plate, per-batch or per-experiment).

Usage

```
normalizePlates(object, scale="additive", log=FALSE, method="median", varianceA
```

Arguments

<code>object</code>	a <code>cellHTS</code> object that has already been configured. See details.
<code>scale</code>	a character specifying the scale of the raw data: "additive" scale (default) or "multiplicative" scale.
<code>log</code>	logical. If <code>log=TRUE</code> , raw data are log ₂ transformed. If data are in additive scale (<code>scale="additive"</code>), <code>log</code> can only be set to <code>log=FALSE</code> . The default is <code>log=FALSE</code> .
<code>method</code>	a character specifying the normalization method to use for performing the per-plate normalization. Allowed values are "median" (default), "mean", "shorth", "POC", "NPI", "negatives", <code>Bscore</code> , <code>loess</code> and <code>locfit</code> . See details.
<code>varianceAdjust</code>	character vector of length one indicating the variance adjustment to perform. Allowed values are "none" (default), "byPlate", "byBatch" and "byExperiment". See details.
<code>posControls</code>	a vector of regular expressions giving the name of the positive control(s). See details.
<code>negControls</code>	a vector of regular expressions giving the name of the negative control(s). See details.
<code>...</code>	Further arguments that get passed on to the function implementing the normalization method chosen by <code>method</code> . Currently, this is only used for <code>Bscore</code> and <code>loess</code> and <code>locfit</code> .

Details

Function `normalizePlates` uses the content of `assayData` slot of `object`. For dual-channel data, the user should first correct for plate effects using `normalizePlates` function, then combine the two channels using function `summarizeChannels`, and finally, if necessary, normalize the summarized intensities calling `normalizePlates` again.

In this function, the normalization is performed in a plate-by-plate fashion, following this workflow:

1. Log transformation of the data (optional, if data are in multiplicative scale);

2. Per-plate normalization using the chosen method;
3. Variance adjustment of the plate intensity corrected data (optional).

The argument `scale` defines the scale of the data. If data are in multiplicative scale (`scale="multiplicative"`), data can be `log2` transformed by setting `log=TRUE`. This changes the scale of the data to "additive".

In the next step of preprocessing, intensities are corrected in a plate-by-plate basis using the chosen normalization method:

- If `method="median"` (median scaling), plates effects are corrected by dividing each measurement by the median value across wells annotated as `sample` in `wellAnno(object)`, for each plate and replicate.
- If `method="mean"` (mean scaling), the average in the `sample` wells is consider instead.
- If `method="shorth"` (scaling by the midpoint of the shorth), for each plate and replicate, the midpoint of the `shorth` of the distribution of values in the wells annotated as `sample` is calculated. Then, every measurement is divided by this value.
- If `method="negatives"` (scaling by the negative controls), for each plate and replicate, each measurement is divided by the median of the measurements on the plate negative controls.

NOTE: Depending on the scale of the data prior to normalization, the above per-plate correction factors are subtracted from each plate measurement, instead.

Other available normalization methods are:

- `method="POC"` (percent of control): for each plate and replicate, each measurement is divided by the average of the measurements on the plate positive controls, and multiplied by 100.
- `method="NPI"` (normalized percent inhibition): each measurement is subtracted from the average of the intensities on the plate positive controls, and this result is divided by the difference between the means of the measurements on the positive and the negative controls.
- `method="Bscore"` (B score): for each plate and replicate, the `B score method` (based on a 2-way median polish) is applied to remove plate effects and row and column biases.
- `method="locfit"` (robust local fit regression): for each plate and replicate, spatial effects are removed by fitting a bivariate local regression (see [spatial normalization function](#)).
- `method="loess"` (loess regression): for each plate and replicate, spatial effects are removed by fitting a loess curve (see [spatial normalization function](#)).

In the final preprocessing step, variance of plate-corrected intensities can be adjusted as follows:

- `varianceAdjust="byPlate"`: per plate normalized intensities are divided by the per-plate median absolute deviations (MAD) in "sample" wells. This is done separately for each replicate and channel;
- `varianceAdjust="byBatch"`: using the content of slot `batch`, plates are split according to assay batches and the individual normalized intensities in each group of plates (batch) are divided by the per-batch of plates MAD values (calculated based on "sample" wells). This is done separately for each replicate and channel;
- `varianceAdjust="byExperiment"`: each normalized measurement is divided by the overall MAD of normalized values in wells containing "sample". This is done separately for each replicate and channel;

By default, no variance adjustment is performed (`varianceAdjust="none"`).

The arguments `posControls` and `negControls` are required for applying the normalization methods based on the control measurements (that is, when `method="POC"`, or `method="NPI"`, or `method="negatives"`). `posControls` and `negControls` should be vectors of regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file (and accessed via `wellAnno(object)`). The length of these vectors should be equal to the current number of channels in `object` (i.e. to the `dim(Data(object))[3]`). By default, if `posControls` is not given, `pos` will be taken as the name for the wells containing positive controls. Similarly, if `negControls` is missing, by default `neg` will be considered as the name used to annotate the negative controls. The content of `posControls` and `negControls` will be passed to `regexpr` for pattern matching within the well annotation given in the `featureData` slot of `object` (which can be accessed via `wellAnno(object)`) (see examples for `summarizeChannels`). The arguments `posControls` and `negControls` are particularly useful in multi-channel data since the controls might be reporter-specific, or after normalizing multi-channel data.

See the Examples section for an example on how this function can be used to apply a robust version of the Z score method, whereby the measurements of each plate and replicate are subtracted by the per-plate median (at sample wells) and then divided by the per-plate MAD (at sample wells).

Value

An object of class `cellHTS` with the normalized data stored in slot `assayData` (its previous contents were overridden). The processing status of the object is updated in the slot `state` to `object@state[["normalized"]]=TRUE`.

Additional slots of `object` may be updated if `method="Bscore"`, or `method="loess"` or `method="locfit"`. Please refer to the help page of the `Bscore` function and `spatialNormalization` function.

## check number of batches:
nbatch(KcViabSmall)
x1 <- normalizePlates(KcViabSmall, scale="multiplicative", log = FALSE, method="median
## End(Not run)

```

oneRowPerId

Rearrange dataframe entries such that there is exactly one row per ID.

Description

Rearrange dataframe entries such that there is exactly one row per ID. The IDs are taken from the argument `ids` and are matched against the first column of `x`. If an ID is missing in `x[, 1]`, a row with NA values is inserted. If an ID occurs multiple times in `x[, 1]`, rows are collapsed into characters of comma-separated values.

Usage

```
oneRowPerId(x, ids)
```

Arguments

<code>x</code>	dataframe.
<code>ids</code>	character vector.

Value

A dataframe whose rows correspond 1:1 to `ids`.

Author(s)

W. Huber (huber@ebi.ac.uk), Ligia Pedroso Bras (ligia@ebi.ac.uk)

Examples

```

x = data.frame(ids=I(c("a", "a", "c")), val=11:13)
oneRowPerId(x, letters[1:3])

```

plate	<i>Retrieve information related with the format of a RNAi experiment</i>
-------	--

Description

These generic functions retrieves information related with the format of RNAi experiment conducted in multi-plate format and stored in an object of `cellHTS` class.

Usage

```
pdim(object)
plate(object)
well(object)
position(object)
```

Arguments

`object` an object of class `cellHTS`.

Value

`pdim` returns a vector of length 2 containing integer values that correspond to the number of rows and columns in a plate. This corresponds to the plate format used in the screen (for example, 96-well or 384-well plates).

`plate` returns a vector of integers with the same length as the product between the number of wells per plate and the number of plates. This gives the plate number for each well in the assay. Corresponds to `fData(object)[, "plate"]`.

`well` returns a character vector containing the wells identifiers (for example "A01", "H06"). Its length equals the product between the number of wells per plate and the number of plates. This vector corresponds to `fData(object)[, "well"]`.

`position` gives a numeric vector containing every well positions (1, 2, 3, ...). Its length is equal to the product between the number of wells per plate and the number of plates.

`cellHTS`

plateEffects	<i>Access plate effects stored in a cellHTS object.</i>
--------------	---

Description

This generic function accesses plate effects stored in slot `rowcol.effects` and `overall.effects` of a `cellHTS` instance.

Usage

```
plateEffects(object)
```

Arguments

object	Object derived from class <code>cellHTS</code> that has been normalized by a spatial normalization method. See details.
--------	---

Value

`plateEffects` returns a list with two elements: `rowcol` and `overall`.

`plateEffects[["rowcol"]]` corresponds to the contents of slot `rowcol.effects` of object. This is a 3D array with the same dimensions as `Data(object):nr of Features x nr of Samples x nr of Channels` of the current `cellHTS` object.

`plateEffects[["overall"]]` contains the data stored in slot `overall.effects` of object. This is a 3D array with dimensions `nr Plates x nr Samples x nr Channels` of object. Slot `overall.effects` is only estimated when B score method is used to normalize the data.

Note that these 2 slots accessed by this function were stored after preprocessing the data either using Bscore method or local regression fit (see `normalizePlates` for details), by setting the option `save.model=TRUE`.

[cellHTS normalizePlates Bscore spatialNormalization](#)

plotSpatialEffects	<i>Plate plot with the row and column offsets estimated by the a spatial normalization method</i>
--------------------	---

Description

The function plots the per-plate row and column effects estimated by the B score method or by the spatial normalization.

Usage

```
plotSpatialEffects(object, channel = 1, plates)
```

Arguments

`object` a `cellHTS` object that has been normalized using the B score method or other spatial normalization (see details).

`channel` a numeric value giving the channel of `object` to plot.

`plates` a vector of integers giving the plate numbers to plot. If missing, the function considers all of the plates.

Details

The function plots the `plate plots` displaying the row and column offsets (stored in slot `rowcol.effects` of the `cellHTS` object) within the plates in `plates`, and for channel `channel`, as determined by the `B score method` or `spatial normalization`. Before plotting the spatial offsets, the values within the chosen channel (argument `channel`) are transformed in order to be confined in the range $[0, 1]$, as follows:

$$y^t = \frac{(y - \min(y))}{\max(y) - \min(y)}$$

Here, y^t are the transformed values, and y the estimated spatial effects. The maximum and the minimum values are calculated using all the values in `plateEffects(object)$rowcol[, , channel]`.

plotSpatialEffects(x, plates=c(1,3))
```

`readHTAnalystData` *Read a set of plate results obtained from a HTanalyser plate reader*

Description

Reads input files (specified by the argument `filenames`) containing replicate data for the same set of assay plates and obtained using an HTanalyser. The number of replicates corresponds to the number of given files (`length(filenames)`), while the total number of plates should be given by the argument `nrPlates`.

Usage

```
readHTAnalystData(filenamees, path=dirname(filenamees), name, nrPlates, verbose=in
```

Arguments

<code>filenamees</code>	vector of characters giving the name(s) of the input file(s) obtained in a HTAnalyser plate reader and containing the set of measurements for each set of replicate plates (see details).
<code>path</code>	can be either a character vector with the same length as <code>filenamees</code> or a character of length 1 indicating the path in which to find the input file(s) <code>filenamees</code> . By default, it can extract the path from <code>filenamees</code> .
<code>name</code>	a character of length 1 with the experiment name.
<code>nrPlates</code>	an integer value indicating the number of plates in the input file(s).
<code>verbose</code>	a logical value, if TRUE, the function reports some of its intermediate progress. Defaults to the state of <code>HYPERLINK(interactive())(interactive())</code> .

Details

This function reads input files obtained in a HTAnalyser plate reader for a multi-plate format screening experiment. Data for the same set of replicate measurements of all plates are expected to come in a single input file. So, the argument `filenamees` should be a character vector specifying the name of the input files for each replicate. Each of these files is expected to contain data for a total of `nrPlates` assay plates. It contains meta-experimental data together with plate measurements in a matrix-like format. The same type of format is expected for each of the `nrPlates` contained in each input file indicated in `filenamees`. The input files should be suitable to be used as input for [readLines](#).

The following metadata fields are expected to be repeated along the input file(s) for each assay plate:

- Microplate format, indicates the plate format used in the screen. Should be the same across plates.
- Barcode, this field is used to uniquely identify each assay plate.
- Method ID, indicates the method used to perform the assay. Should be the same for every plate.
- Data, indicates the type of data and should be the same for every plate.
- Units, indicates the units of the readings. Should be the same for every plate.
- Display format, indicating the numeric format used to display the data measurements. Should be the same along plates.

This function expects that the next line after the meta field "Display format" for a given plate contains the column numbers (`1:ncol`) which are then followed by the matrix of measurements in each well. Each entry of the data matrix corresponds to a position in the assay plate with coordinates (`row, col`), except the first column, which gives the row ID, as upper letters (A, B, ...).

Value

An object of class `cellHTS`, which extends the class `NChannelSet`. After calling this function, the content of the following slots is as follows:

assayData	an object of class <code>AssayData</code> containing the imported measurement data. Each matrix represents a single channel, and each sample (replicate) corresponds to a column. Thus, the total number of rows in each matrix corresponds to the product between the number of wells per plate and the number of assay plates.
phenoData	the argument name is stored in its column <code>assay</code> .
featureData	the information about the plate and well identifiers for each plate measurement are stored in columns <code>plate</code> and <code>well</code> of this slot.
intensityFiles	a list, where each component contains a copy of the measurement data of a given plate, replicate and channel. Its length corresponds to the number of rows of <code>plateList</code> .
plateList	a <code>data.frame</code> containing the columns "Filename", "Plate", "Replicate", "Channel" and "status". Each row of this slot makes the correspondence between a given component (name given in column "Filename") in the list stored in slot <code>intensityFiles</code> (i.e. <code>plate</code>) and its respective plate, replicate and channel number. Thus, this <code>data.frame</code> contains as many rows as the product between the total number of plates, replicates and channels. The last column named <code>status</code> is of type character and contains the string "OK" indicated the success status of the data import.

Author(s)

W. Huber (huber@ebi.ac.uk), Ligia Bras (ligia@ebi.ac.uk)

References

Boutros, M., Bras, L.P. and Huber, W. (2006) Analysis of cell-based RNAi screens, *Genome Biology* 7, R66.

See Also

To read a collection of plate result files with measurements of a single plate and replicate, see [readPlateList](#).

Examples

```
datadir <- system.file("KcCellTiter", package = "cellHTS2")
x <- readHTAnalystData(filenamees = c("KcCellTiter0607.txt", "KcCellTiter0707.txt"), n
x <- configure(x, confFile = "Plateconf.txt", logFile="Screenlog.txt", descripFile =
  path = datadir)
```

readPlateList

Read a collection of plate reader data files

Description

Reads a collection of plate reader data files into a `cellHTS` object. The names of the files, plus additional information (plate number, repeat number, assay/treatment/condition) is expected in a tab-delimited table specified by the argument `filename`.

Usage

```
readPlateList(filename, path=dirname(filename), name, importFun, verbose=interac
```

Arguments

filename	the name of the file table (see details). This argument is just passed on to the read.table function, so any of the valid argument types for read.table are valid here, too.
path	a character of length 1 indicating the path in which to find the plate reader files.
name	a character of length 1 with the experiment name.
importFun	a function to read the data files. The default function works for a certain file format, such as that of the example files provided with this package. If your plate reader software produces files with a different format, the import function needs to be adapted. See details.
verbose	a logical value, if TRUE, the function reports some of its intermediate progress.

Details

The file table is expected to be a tab-delimited file with at least three columns named `Filename`, `Plate`, and `Replicate`. The contents of the columns `Plate` and `Replicate` are expected to be integers. Further columns are allowed, and can be used to denote, for example, different variants of the assay, treatments, incubation times, conditions, etc.

`importFun` can be used to define a custom function to import data files. The `importFun` function should accept as its first argument names from the `Filename` column of the file table (which in principle do not need to be individual files, they could also be handles for database entries or pointers into relevant parts of a file). It should return a list with two components:

- The first component should be a `data.frame` with the following columns
 - `well`, a character vector with the well identifier in the plate.
 - `val`, the intensity values measured in that well.
 and with as many rows as there are wells in the plate.
- The second component should be a character vector containing a copy of the imported input data file (such as the output of [readLines](#)). It should be suitable to be used as input for [writeLines](#), since it will be used to reproduce the intensity files that are linked in the HTML quality reports generated by [writeReport](#).

For example, to import plate data files from EnVision plate reader, set `importFun=getEnVisionRawData` or `importFun=getEnvisionCrosstalkCorrectedData`. See function [getEnVisionRawData](#).

Value

An object of class `cellHTS`, which extends the class `NChannelSet`. After calling this function, the content of the following slots is as follows:

assayData	an object of class <code>AssayData</code> containing the imported measurement data. Each matrix represents a single channel, and each run corresponds to a column. Thus, the total number of rows in each matrix corresponds to the product between the number of wells per plate and the number of assay plates.
phenoData	information about the runs, inferred from the <code>plateList</code> file: which replicate, which variant of the assay, treatment, incubation times etc.

`featureData` the information about the plate and well identifiers for each plate measurement are stored in columns `plate` and `well` of this slot.

`plateList` a data.frame containing what was read from input file `x`, plus a column `status` of type character: it contains the string "OK" if the data import appeared to have gone well, and the respective error or warning message otherwise.

`intensityFiles` a list, where each component contains a copy of the imported input data files. Its length corresponds to the number of rows of `plateList`.

`scoreReplicates` *Scores normalized replicate values given in a cellHTS object*

Description

This function scores the normalized replicate values stored in slot `assayData` of a `cellHTS` object. Current available options are to take the z -score value or the per-replicate normalized percent inhibition (NPI). Data are stored in slot `assayData` overriding its current content.

Usage

```
scoreReplicates(object, sign="+", method="zscore", ...)
```

Arguments

<code>object</code>	an object of class <code>cellHTS</code> that has already been normalized.
<code>sign</code>	a character string, either "+" (default) or "-", which corresponds to multiplying the data by +1 or -1, respectively, after applying the scoring method specified by argument <code>method</code> . See details.
<code>method</code>	a character string indicating which method to use to score the replicate measurements. Available options are "none", "zscore" (default), "NPI". See details.
<code>...</code>	additional parameters required by some of the methods chosen in <code>method</code> .

Details

This function scores the normalized values given in the slot `assayData` of `object`. Current available scoring methods are:

- `method="none"`, no scoring is applied.
- `method="zscore"` (robust z-scores), for each replicate, this is calculated by subtracting the overall median from each measurement and dividing the result by the overall `mad`. These are estimated for each replicate by considering the distribution of intensities (over all plates) in the wells whose content is annotated as `sample`.
- `method="NPI"` (normalized percent inhibition applied in a per-replicate basis, i.e. using the overall mean of positive and negative controls across all plates of a given replicate), for each replicate, this method consists of subtracting each measurement from the average of the intensities on the positive controls (taken across all plates), and this result is then divided by the difference between the averages of the measurements on the positive and the negative controls (taken across all plates). If this method is chosen, one may need to provide further arguments to `scoreReplicates`, namely, arguments `posControls` and `negControls`. These arguments should be vectors of regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file. The length of these vectors should match the current number of channels in `object` (i.e. `dim(Data(object))[3]`). By default, if `posControls` or `negControls` are not given, `pos` and `neg` will be taken as the name for the wells containing positive or negative controls. The content of `posControls` and `negControls` is passed to `regexpr` for pattern matching within the well annotation given in the `featureData` slot of `object` (which can be accessed via `wellAnno(object)`) (see examples for `summarizeChannels`).

After replicate scoring using the chosen method, the value given in `sign` ("+" or "-") is used to set the sign of the calculated scores. For example, with a `sign="-"`, a strong decrease in the signal will be represented by a positive score, whereas setting `sign="+"`, such a phenotype will be represented by a negative score. This option can be set to calculate the results to the commonly used convention.

Value

A `cellHTS` object with its slot `assayData` replaced with the scored values (same dimension).

Important: Note that the processing state "scored" of the `cellHTS` object is only updated to `TRUE` after summarizing the replicates, which is the next preprocessing step (see `summarizeReplicates`).

x <- summarizeReplicates(x, summary="min") # conservative approach
```

scores2calls

Sigmoidal transformation of the score values stored in a cellHTS object obtaining the call values for each probe.

Description

Apply a sigmoidal transformation with parameters `z0` and `lambda` to the summarized scored values stored in a `cellHTS` object. The obtained results are called *calls* and are stored in slot `assayData`, overriding its current content.

Currently this function is implemented only for single-color data.

Usage

```
scores2calls(x, z0, lambda)
```

Arguments

<code>x</code>	an object of class <code>cellHTS</code> containing replicate data that have already been scored and summarized (see details).
<code>z0</code>	a numeric value giving the centre of the sigmoidal transformation. See details.
<code>lambda</code>	a numeric value (>0) that corresponds to the parameter <code>lambda</code> of the sigmoidal transformation. This value should be >0 , but usually it makes more sense to use a value ≥ 1 . See details.

Details

This function applies a sigmoidal transformation with parameters `z0` and `lambda` to the single probe score values stored in a `cellHTS` object. The obtained results are called *calls*. The transformation is given by:

$$1/(1 + \exp(-\lambda * (z - z0)))$$

where z are the score values, $z0$ is the centre of the sigmoidal transformation, and the `lambda` is a parameter that controls the smoothness of the transformation. The higher is `lambda`, more steeper is the transition from lower to higher values. `lambda` should be > 0 , but usually it makes more sense to use a value ≥ 1 .

This transformation maps the score values to the interval $[0, 1]$, and is intended to expand the scale of scores with intermediate values and shrink the ones showing extreme values, therefore making the difference between intermediate phenotypes larger.

Value

The `cellHTS` object with the call values stored in slot `assayData`. This is an object of class `assayData` corresponding to a single matrix of dimensions `Features` \times 1.

[normalizePlates](#), [summarizeChannels](#), [scoreReplicates](#), [summarizeReplicates](#), [imageScreen](#).

Examples

```
data(KcViabSmall)
x <- normalizePlates(KcViabSmall, scale="multiplicative", method="median", varianceAd
x <- scoreReplicates(x, sign="-", method="zscore")
x <- summarizeReplicates(x, summary="min")
xc <- scores2calls(x, z0=1.5, lambda=2)
plot(Data(x), Data(xc), col="blue", xlab="z-scores", ylab="calls", main=expression(1/
if(require(splots)) {
  sp = split(Data(xc), plate(xc))
  grid.newpage()
  plotScreen(sp, zrange=c(0,1), fill=c("white", "red"), na.fill="yellow",
            main="Calls", ncol=3L)
}
```

spatialNormalization

Spatial normalization

Description

Correction of spatial plate effects of data stored in slot `assayData` of a `cellHTS` object by fitting a polynomial surface within each plate using local regression ([loess](#) or [robust local fit](#)). Uses a second degree polynomial (local quadratic fit). Only wells containing "sample" are considered to fit the models.

Usage

```
spatialNormalization(object, model="locfit", smoothPar=0.6, save.model=FALSE)
```

Arguments

<code>object</code>	a <code>cellHTS</code> object that has already been configured.
<code>model</code>	character indicated whether the polynomial surface should be fitted using robust "locfit" or "loess". The default is "locfit".
<code>smoothPar</code>	numeric. The default is <code>smoothPar=0.6</code> . The parameter which controls the degree of smoothing (corresponds to 'span' argument of <code>loess</code> , or to the parameter 'nn' of <code>lp</code> of <code>locfit</code>).
<code>save.model</code>	a logical value specifying whether the per-plate spatial effects should be stored in slot <code>rowcol.effects</code> of <code>object</code> . See details.

Details

For convenience, this function should be called indirectly from `normalizePlates` function.

The normalization is performed separately for each replicate and channel, in a per-plate fashion using the chosen local regression model. The polynomial surfaces are fitted using the wells containing "sample".

If `save.model=TRUE`, the models row and column offsets are stored in the slot `rowcol.effects` of `object`.

Value

An object of class `cellHTS` with normalized data stored in slot `assayData`. Furthermore, if `save.model=TRUE`, the row and column estimated offsets are stored in the slot `rowcol.effects`. This slot is a 3D array with the same dimension as `Data(object)`.

Moreover, the processing status of the `cellHTS` object is updated in the slot `state` to `object@state[["normalized"]]`.

Author(s)

Ligia Bras (ligia@ebi.ac.uk)

Examples

```
data(KcViabSmall)
x <- KcViabSmall
xs <- spatialNormalization(x, model="loess", save.model = TRUE)
## Calling spatialNormalization function from "normalizePlates":
xopt <- normalizePlates(x, method="loess", varianceAdjust="none", save.model = TRUE)
all(xs@rowcol.effects == xopt@rowcol.effects, na.rm=TRUE)
```

state	<i>Retrieve the state of a cellHTS object.</i>
-------	--

Description

This generic function accesses the state of an object derived from the `cellHTS` class.

Usage

```
state(object)
```

Arguments

`object` an object of class `cellHTS`.

Value

`state` returns a logical vector corresponding to the contents of slot `state` of `object`.

Author(s)

Ligia Bras <ligia@ebi.ac.uk>

See Also

`cellHTS`

summarizeChannels	<i>Summarization of dual-channel data</i>
-------------------	---

Description

Combines plate intensities (raw or already corrected in a per-plate fashion) from dual-channel data stored in slot `assayData` of a `cellHTS` instance by applying the function defined in `fun`.

Usage

```
summarizeChannels(object,  
  fun = function(r1, r2, thresh) ifelse(r1>thresh, r2/r1, as.numeric(NA)))
```

Arguments

`object` an object of class `cellHTS` that has been configured. See details.

`fun` a user-defined function for the two channel summarization. `fun` takes two numeric vectors and returns a numeric vector of the same length. The default is to take the ratio between the second and first channels, with a threshold on `r1` shown above in the *Usage* section that should be set by the user.

Details

For each plate and replicate of a two-color experiment, the function defined in `fun` is applied to relate the intensity values in the two channels of the `cellHTS` object. The default is to take the ratio between the second and first channels, with a threshold on `r1` (see the *Usage* section). This threshold should be adjusted by the user according to the data. For an example, see the *Examples* section. This function uses the content of slot `assayData` of `object` and can be applied either to raw data or after per-plate correction of the intensity values in each channel using function `normalizePlates`. This choice depends on channel summarization method that one intends to apply (i.e., the function given by argument `fun`).

Value

An object of class `cellHTS` with the summarized dual-channel intensities stored in slot `assayData`. This is an object of class `assayData` containing one matrix with the summarized channel data (dimensions `nrFeatures` x `nrSamples`).

Author(s)

Ligia Bras (ligia@ebi.ac.uk), Wolfgang Huber (huber@ebi.ac.uk)

References

Boutros, M., Bras, L.P. and Huber, W. (2006) Analysis of cell-based RNAi screens, *Genome Biology* **7**, R66.

See Also

`normalizePlates`, `scoreReplicates`, `summarizeReplicates`.

Examples

```
data(dualCh)
x <- dualCh
table(wellAnno(x))

## Define the controls for the different channels:
negControls=vector("character", length=dim(Data(x))[3])

## channel 1 - gene A
## case-insensitive and match the empty string at the beginning and end of a line (to
negControls[1]= "(?i)^geneA$"
## channel 2 - gene A and geneB
negControls[2]= "(?i)^geneA$|^geneB$"
posControls = vector("character", length=dim(Data(x))[3])
## channel 1 - no controls
## channel 2 - geneC and geneD
posControls[2]="(?i)^geneC$|^geneD$"
## Not run:
writeReport(cellHTSlist=list("raw"=x), map=TRUE, plotPlateArgs=TRUE, posControls=posC

## End(Not run)
## In this example, we first normalize each channel separately by
## plate median scaling (no variance adjustment), since we need to make the measureme
## comparable across plates for the next step of channel summarization:
```

```

        xn = normalizePlates(x, scale="multiplicative", log=FALSE, method="median", varia
## Then, we define a low intensity threshold for the measurements in the constitutive
## which will be set to the 5
## and take the ratio R2/R1.
        xn = summarizeChannels(xn, fun = function(r1, r2,
            thresh=quantile(r1, probs=0.05, na.rm=TRUE)) ifelse(r1>thresh, r2/r1, as.num
## After channel summarization, we take the log2 and apply plate median normalization
## and opt to not adjust the variance:
xn = normalizePlates(xn, scale="multiplicative", log=TRUE, method="median", varianceA
## Define the controls for the normalized and summarized intensities (only one channe
negControls = vector("character", length=dim(Data(xn))[3])
## For the single channel, the negative controls are geneA and geneB
negControls[1]= "(?i)^geneA$|^geneB$"
posControls = vector("character", length=dim(Data(xn))[3])
## For the single channel, the negative controls are geneC and geneD
posControls[1]=" (?i)^geneC$|^geneD$"
## Not run:
writeReport(cellHTSlist=list("raw"=x, "normalized"=xn), force=TRUE, map=TRUE, plotPla
        posControls=posControls, negControls=negControls)

## End(Not run)

## Another option could be to just take the log2 of the ratio between R2 and R1 raw i
xn1 = summarizeChannels(x, fun = function(r1, r2) log2(r2/r1))

```

```
summarizeReplicates
```

Summarize between scored replicate values given in a cellHTS object to obtain a single value for each probe

Description

This function summarizes the replicate values stored in slot `assayData` of a `cellHTS` object and calculates a single score for each probe. Data are stored in slot `assayData` overriding its current content.

Currently this function is implemented only for single-color data.

Usage

```
summarizeReplicates(object, summary = "min")
```

Arguments

<code>object</code>	an object of class <code>cellHTS</code> that has already been normalized and scored (see details).
<code>summary</code>	a character string indicating how to summarize between replicate measurements. One of "min" (default), "mean", "median", "max", "rms", "closestToZero", or "FurthestFromZero" can be used (see details).

Details

A single value per probe is calculated by summarizing between scored replicates stored in the slot `assayData` of `object`. The summary is performed as follows:

- If `summary="mean"`, the average of replicate values is considered;
- If `summary="median"`, the median of replicate values is considered;
- If `summary="max"`, the maximum of replicate intensities is taken;
- If `summary="min"`, the minimum is considered, instead;
- If `summary="rms"`, the square root of the mean squared value of the replicates (root mean square) is taken as a summary function;
- If `summary="closestToZero"`, the value closest to zero is taken as a summary (useful when both sides of the distribution of z-score values are of interest);
- If `summary="furthestFromZero"`, the value furthest from zero is taken as a summary (useful when both sides of the distribution of z-score values are of interest).

Value

The `cellHTS` object with the summarized scored values stored in slot `assayData`. This is an object of class `assayData` corresponding to a single matrix of dimensions `Features` x `1`. Moreover, the processing status of the `cellHTS` object is updated in the slot `state` to `object@state[["scored"]]=TRUE`.

Examples

```
data(KcViabSmall)
# normalize
x <- normalizePlates(KcViabSmall, scale="multiplicative", method="median", varianceAd
# score the replicates
x <- scoreReplicates(x, sign="-", method="zscore")
# summarize the replicates (conservative approach: take the minimum value between rep
x <- summarizeReplicates(x, summary="min")
```

`templateDescriptionFile`*Creates a template description file for an RNAi experiment*

Description

This function creates a template description file for an RNAi experiment with default entries compliant with MIAME class and with additional entries specific for a `cellHTS` object.

Usage

```
templateDescriptionFile(filename="Description.txt", path, force=FALSE)
```

Arguments

<code>filename</code>	the name of the output file. Default is "Description.txt".
<code>path</code>	a character of length 1 indicating the path in which to create the screen description file. By default, it can extract the path from <code>filename</code> .
<code>force</code>	a logical value, determines the behaviour of the function if file <code>filename</code> exists. If <code>force</code> is <code>TRUE</code> , the function overwrites <code>filename</code> , otherwise it casts an error.

Details

This function can be called to generate a template file for the RNAi experiment. This file contains the fields that are compliant with the `MIAME` class and also additional entries specific for the `cellHTS` class, which should be edited and completed by the user.

This file, which we call *Screen description file*, is required to configure the `cellHTS` object via function `configure`. It is intended to contain general information about the screen, such as its title, its goal, when and how it was performed, which organism, which library, type of assay, references, and any other information that is pertinent to the biological interpretation of the experiments.

Value

The function returns a character with the full path and name of the file that was created.

[configure](#)

Examples

```
out <- templateDescriptionFile("Description.txt", path=tempdir())
out
readLines(out)
```

wellAnno *Access the annotation from a cellHTS object.*

Description

These generic functions access the annotation data stored in the `featureData` slot of an object of class `cellHTS`.

Usage

```
wellAnno(object)
geneAnno(object)
```

Arguments

`object` Object derived from class `cellHTS`.

Value

`wellAnno` returns a `factor` of length equal to the total number of features (number of plates x number of wells per plate) indicating the contents of the wells. Corresponds to `fData(object)[, "controlStatus"]`.

`geneAnno` returns a vector of the same length as the number of features in `object` (number of plates x number of wells per plate) containing the gene IDs used in the screen. This corresponds to the contents of `fData(object)[, "GeneID"]`.

See `cellHTS` class for details.

`write.table`

Examples

```
data(KcViabSmall)
x <- KcViabSmall
## determine the ratio between each well and the plate median
xraw <- Data(x)
y <- array(as.numeric(NA), dim=dim(xraw))
nrWell <- prod(pdims(x))

for(p in 1:max(plate(x))) {
  ind <- (1:nrWell)+nrWell*(p-1)
  samples <- (wellAnno(x)[ind]=="sample")
  y[ind, ,] <- apply(xraw[ind, , ,drop=FALSE], 2:3, function(w) w/median(w[samples],
  )
  y <- signif(y, 4)
  out <- y[,,1]
  out <- cbind(geneAnno(x), wellAnno(x), out)
  colnames(out) <- c("GeneID", "wellAnno",
    sprintf("Well/Median_r%d_ch%d", rep(1:dim(y)[2], dim(y)[3]), rep(1:dim(y)[3], each=
write.tabdel(out, file = tempfile())
```

writeReport

Create a directory with HTML pages of linked tables and plots documenting the contents of a cellHTS experiment

Description

Creates a directory with HTML pages of linked tables and plots documenting the contents of the preprocessing of a `cellHTS` object.

Usage

```
writeReport (cellHTSlist,
            outdir,
            force=FALSE,
            map=FALSE,
            plotPlateArgs=FALSE,
            imageScreenArgs=NULL,
            progressReport = interactive(),
            posControls,
            negControls)
```

Arguments

`cellHTSlist` a list of `cellHTS` objects. See details.

`outdir` a character of length 1 with the name of a directory where to write the report HTML file and images. If the directory does not exist, it is created. If it exists and is not empty, then the behaviour depends on the value of `force`. If `outdir` is missing, it is set to `file.path(getwd(), name(cellHTSlist[['xraw']]))`, i.e. a directory with the name of the cellHTS object(s) in the current working path.

`force` a logical value, determines the behaviour of the function if `outdir` exists and is not empty. If `force` is `TRUE`, the function overwrites (removes and recreates) `outdir`, otherwise it casts an error.

`map` a logical value indicating whether tooltips with the annotation should be added to the plate plots and image screen. Default value is `FALSE`.

`plotPlateArgs` either a list with parameters for the plate plots of the per plate quality report pages, or a logical scalar with values `FALSE` or `TRUE`. If `FALSE`, the plate plots are omitted, this option is here because the production of the plate plots takes a long time. See details.

`imageScreenArgs` a list with parameters for the function `imageScreen`. See details.

`progressReport` a logical, should a progress report window be displayed?

`posControls` a list or vector of regular expressions specifying the name of the positive controls. See details.

`negControls` a vector of regular expressions specifying the name of the negative controls. See details.

Details

Argument `cellHTSlist` should be a list containing at least one component named "raw" which corresponds to an unnormalized `cellHTS` object (i.e. `state(cellHTSlist[["raw"]])["normalized"]=FALSE`). Other possible components of `cellHTSlist` can be:

- "normalized": a `cellHTS` object containing normalized data (i.e. `state(cellHTSlist[["normalized"]])["normalized"]=TRUE` and `state(cellHTSlist[["normalized"]])["scored"]=FALSE`).
- "scored": a `cellHTS` object containing data scored data (i.e. `state(cellHTSlist[["scored"]])["scored"]=TRUE`). If this component is available, then `cellHTSlist[["normalized"]]` should also be given.

All of the components of `cellHTSlist` should be `cellHTS` objects containing data from the same experiment, but in different preprocessing stages.

The following elements are recognized for `plotPlateArgs` and passed on to `plotPlate`: `sdcol`, the color scheme for the standard deviation plate plot, `sdrange`, the sd range to which the colors are mapped, `xcol`, the color scheme for the intensity plate plot, `xrange`, the intensity range to which the colors are mapped. If an element is not specified, default values are used.

The following elements are recognized for `imageScreenArgs` and passed on to `imageScreen`: `ar`, aspect ratio, `zrange`, range, `anno`, gene annotation for the image map (if `map=TRUE`).

`posControls` and `negControls` should be given as a vector of regular expression patterns specifying the name of the positive(s) and negative(s) controls, respectively, as provided in the plate configuration file (and accessed via `wellAnno(objects)`).

If the `cellHTS` object containing normalized data was provided in `cellHTSlist`, the length of `posControls` and `negControls` should be equal to the number of channels in this `cellHTS` object (`dim(Data(cellHTSlist[["normalized"]]))[3]`). Otherwise, the length of these vectors should be equal to the number of channels in the unprocessed `cellHTS` object (i.e., `dim(Data(cellHTSlist[["raw"]]))[3]`).

By default, if `posControls` is not given, "pos" will be taken as the name for the wells containing positive controls. Similarly, if `negControls` is missing, by default "neg" will be considered as the name used to annotate the negative controls. The content of `posControls` and `negControls` will be passed to `regexpr` for pattern matching within the well annotation given in column `controlStatus` of the `featureData` slot of the `cellHTS` object. If no controls are available for a given channel, use "" or NA for that channel. For example, `posControls = c("", "(?i)^diap$")` means that channel 1 has no positive controls, while "diap" is the positive control for channel 2.

The arguments `posControls` and `negControls` are particularly useful in multi-channel data since the controls might be reporter-specific, or after normalizing multi-channel data.

In the case of a two-way assay, where two types of "positive" controls are used in the screen ("activators" and "inhibitors"), `posControls` should be defined as a list with two components (called `act` and `inh`), each of which should be vectors of regular expressions of the same length as the current number of reporters (as explained above).

By default, tooltips doing the mapping between the probe annotation and the plate wells are not added to the plate plots and to the overall screen plot. If any of the `cellHTS` objects in `cellHTSlist` is annotated, the probe annotation uses the information contained whether in column `GeneSymbol` or column `GeneID` (if the former is missing) of the `featureData` slot of the annotated `cellHTS` object. Otherwise, the mapping simply uses the well identifiers.

Value

The function is called for its side-effect. It returns a character with the full path and name of the report index file, this is an HTML file which can be read by a web browser.

## End(Not run)

```

writeTab

Write the data from a cellHTS object to a tab-delimited file

Description

Write the data from a [cellHTS](#) object to a tab-delimited file.

Usage

```

## S4 method for signature 'cellHTS':
writeTab(x, file=paste(name(x), "txt", sep="."))

```

Arguments

`x` a [cellHTS](#) object.
`file` the name of the output file.

Details

This function is a wrapper for function [write.table](#) to write the contents of `assayData` slot of a [cellHTS](#) object to a tab-delimited file. If the object is already annotated, the probe information (`fData(object)@GeneID`) is also added.

Value

The name of the file that was written.
