aracne

Algorithm for the Reconstruction of Accurate Cellular NEtworks

Description

This function takes the mutual information matrix as input in order to return the infered network according to the Aracne algorithm. This algorithm applies the data processing inequality to all triplets of nodes in order to remove the least significant edge in each triplet.

Usage

```
aracne( mim, eps=0 )
```

Arguments

mim	A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see build.mim.
eps	Numeric value indicating the threshold used when removing an edge: for each triplet of nodes (i,j,k) , the weakest edge, say (ij) , is removed if its weight is below $\min\{(ik),(jk)\}$ -eps - see references.

Details

The Aracne procedure starts by assigning to each pair of nodes a weight equal to their mutual information. Then, the weakest edge of each triplet is interpreted as an indirect interaction and is removed if the difference between the two lowest weights is above a threshold eps.

Value

arache returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following command: plot(as(returned.matrix , "graphNEL"))

net <- aracne(mim)</pre>
```

build.mim

Build Mutual Information Matrix

Description

build.mim takes the dataset as input and computes the mutual information beetween all pair of variables according to the mutual inforantion estimator estimator. The results are saved in the mutual information matrix (MIM), a square matrix whose (i,j) element is the mutual information between variables X_i and X_j .

Usage

```
build.mim(data, estimator="mi.empirical")
```

Arguments

data data.frame containing gene expression data or any dataset where columns con-

tain variables/features and rows contain outcomes/samples.

estimator The name of the mutual information estimator. The package implements four es-

timators: "mi.empirical", "mi.mm", "mi.shrink", "mi.sg" (default: "mi.empirical") - see details. These estimators require discrete data values - see discretize.

Details

- "mi.empirical": This estimator computes the entropy of the empirical probability distribution.
- "mi.mm" : This is the Miller-Madow asymptotic bias corrected empirical estimator.
- "mi.shrink": This is a shrinkage estimate of the entropy of a Dirichlet probability distribution.
- "mi.sg": This is the Schurmann-Grassberger estimate of the entropy of a Dirichlet probability distribution.

Value

build.mim returns the mutual information matrix.

```
data(syn.data)
#mutual information estimator
estimator="mi.empirical"
#number of bins used to discretize
nb.bins = sqrt(nrow(syn.data))
mim <- build.mim(discretize(syn.data,nbins=nb.bins),estimator)</pre>
```

clr

Context Likelihood or Relatedness Network

Description

clr takes the mutual information matrix as input in order to return the infered network - see details.

Usage

```
clr( mim )
```

Arguments

mim

A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see build.mim.

Details

The CLR algorithm is an extension of relevance network. Instead of considering the mutual information $I(X_i; X_j)$ between features X_i and X_j , it takes into account the score $\sqrt{z_i^2 + z_j^2}$, where

$$z_i = \max\left\{0, \frac{I(X_i; X_j) - \mu_i}{\sigma_i}\right\}$$

and μ_i and σ_i are, respectively, the mean and the standard deviation of the empirical distribution of the mutual information values $I(X_i; X_k)$, k=1,...,n.

4 discretize

Value

clr returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following comand plot(as(returned.matrix ,"graphNEL"))

net <- clr(mim)</pre>
```

discretize

Unsupervized Data Discretization

Description

discretize discretizes data using the equal frequencies or equal width binning algorithm. "equalwidth" and "equalfreq" discretizes each random variable (each column) of the data into nbins. "globalequalwidth" discretizes the range of the random vector data into nbins.

Usage

```
discretize( data, disc="equalfreq", nbins=sqrt(nrow(data)) )
```

Arguments

data	A data.frame containing data to be discretized. The columns contains variables and the rows samples.
disc	The name of the discretization method to be used :"equalfreq", "equalwidth" or "globalequalwidth" (default : "equalfreq") - see references.
nbins	Integer specifying the number of bins to be used for the discretization. By default the number of bins is set to \sqrt{N} where N is the number of samples.

Value

discretize returns the discretized dataset.

```

minet

Mutual Information Network

Description

For a given dataset, minet infers the network in two steps. First, the mutual information between all pairs of variables in dataset is computed according to the estimator argument. Then the algorithm given by method considers the estimated mutual informations in order to build the network.

Usage

Arguments

dataset	$data. frame\ where\ columns\ contain\ variables/features\ and\ rows\ contain\ outcomes/samples.$
method	The name of the inference algorithm: "clr", "aracne" or "mrnet" (default: "mrnet") - see references.
estimator	The name of the mutual information estimator: "mi.empirical", "mi.mm", "mi.shrink" or "mi.sg"(default: "mi.empirical") - see build.mim.
disc	The name of the discretization method to be used: "equalfreq" or "equalwidth" (default: "equalfreq") - see discretize.
nbins	Integer giving the number of bins to be used in the discretization.

Value

minet returns a matrix which is the weighted adjacency matrix of the network. The weights range from 0 to 1 and can be seen as a confidence measure on the presence of the arcs. In order to display the network, load the package Rgraphviz and use the following command: plot(as(returned.matrix , "graphNEL"))

mrnet

Maximum Relevance Minimum Redundancy

Description

mrnet takes the mutual information matrix as input in order to infer the network using the maximum relevance/minimum redundancy feature selection method - see details.

Usage

```
mrnet( mim )
```

Arguments

mim

A square matrix whose i,j th element is the mutual information between variables Xi and Xj - see build.mim.

Details

The MRNET approach consists in repeating a MRMR feature selection procedure for each variable of the dataset. The MRMR method starts by selecting the variable X_i having the highest mutual information with the target Y. In the following steps, given a set $\mathcal S$ of selected variables, the criterion updates $\mathcal S$ by choosing the variable X_k that maximizes $I(X_k;Y) - \frac{1}{|\mathcal S|} \sum_{X_i \in \mathcal S} I(X_k;X_i)$

The weight of each pair X_i, X_j will be the maximum score between the one computed when X_i is the target and the one computed when X_j is the target.

norm 7

Value

mrnet returns a matrix which is the weighted adjacency matrix of the network. In order to display the network, load the package Rgraphviz and use the following command: plot(as(returned.matrix , "graphNEL"))

net <- mrnet(mim)</pre>
```

norm

Data Normalization

Description

Normalizes data x using the following code : $(x - \min(x))/(\max(x - \min(x)))$.

Usage

```
norm(x)
```

Arguments

Х

A data frame or matrix or vector containing the data to be normalized. In this package the norm method is used to normalize the network's weighted adjacency matrices.

Value

norm returns the data.frame x with normalized values (i.e. values ranging from 0 to 1)

Examples

```
data <- runif(100,-10,10)
ndata <- norm(data)</pre>
```

8 syn.net

syn.data

Simulated Gene Expression Data

Description

Dataset containing 100 samples and 50 genes generated by the publicly available SynTReN generator using a yeast source network - see syn.net

Usage

```
data(syn.data)
```

Format

syn.data is a data frame containing 100 rows and 50 columns. Each row contains a microarray experiment and each column contains a gene.

Source

```
SynTReN 1.1.3 with source network: yeast\_nn.sif
```

References

Examples

```
data(syn.data)
data(syn.net)
syn.data <- discretize(syn.data)
mim <- build.mim(syn.data)
infered.net <- mrnet(mim)
max(fscores(validate(infered.net, syn.net)))</pre>
```

syn.net

SynTReN Source Network

Description

This is the true underlying network used to generate the dataset loaded by data(syn.data) - see syn.data.

Usage

```
data(syn.net)
```

validate 9

Format

syn.net is a boolean adjacency matrix representing an undirected graph of 50 nodes.

Source

syn.net is the "yeast_nn.sif" source network from the SynTReN generator where all the variables/nodes not in syn.data were removed.

References

Tim Van den Bulcke, Koenraad Van Leemput, Bart Naudts, Piet van Remortel, Hongwu Ma, Alain Verschoren, Bart De Moor, and Kathleen Marchal. Syntren: a generator of synthetic gene expression dataset for design and analysis of structure learning algorithms. BMC Bioinformatics, 2006.

Examples

```
data(syn.data)
data(syn.net)
mim <- build.mim(discretize(syn.data),estimator="mi.empirical")
infered.net <- mrnet(mim)
max(fscores(validate(infered.net, syn.net)))</pre>
```

validate

Inference Validation

Description

validate compares the infered network to the true underlying network for several threshold values and appends the resulting confusion matrices to the returned object.

Usage

```
validate( inet, tnet, steps=50 )
```

Arguments

inet	This is the infered network, a data.frame or matrix obtained by one of the functions minet, aracne, clr or mrnet.
tnet	The true underlying network. This network must have the same size and variable names as inet.
steps	The number of threshold values to be used in the validation process - see details.

Details

For each of the steps threshold values I_0 , the edges whose weight are (strictly) below I_0 are eliminated. All the other edges will have a weight 1. Thus for each threshold, we obtain a boolean network from the infered network. This network is compared to the true underlying network, tnet, in order to compute a confusion (adjacency) matrix. All the confusion matrices, obtained with different threshold values, are appended to the returned object. In the end the validate function returns a data frame containing steps confusion matrices.

vis.res

Value

validate returns a data.frame whith four columns named thrsh, tp, fp, fn. These values are computed for each of the steps thresholds. Thus each row of the returned object contains the confusion matrix for a different threshold.

minet, vis.res
```

Examples

```
data(syn.data)
data(syn.net)
inf.net <- mrnet(build.mim(discretize(syn.data)))
table <- validate(inf.net, syn.net, steps=100)</pre>
```

vis.res

Visualize Results

Description

A group of functions to plot precision-recall and ROC curves and to compute f-scores from the data.frame returned by the validate function.

Usage

```
pr(table)
rates(table)
fscores(table, beta=1)
show.pr(table,device=-1,...)
show.roc(table,device=-1,...)
```

Arguments

table	This is the (steps x 5) data.frame returned by the validate function where steps is the number of thresholds used in the validation process and where columns contain TP,FP,TN,FN values (confusion matrix) as well as the threshold value used - see validate.
beta	Numeric used as the weight of the recall in the f-score formula - see details. The default value of this argument is 1, meaning precision as important as recall.
device	The device to be used. This parameter allows the user to plot precision-recall and receiver operating characteristic curves for various inference algorithms on the same plotting window - see examples.
	arguments passed to plot

vis.res 11

Details

A confusion matrix contains FP,TP,FN,FP values.

- "true positive rate" $tpr = \frac{TP}{TN+TP}$
- "false positive rate" $fpr = \frac{FP}{FN + FP}$
- "precision" $p = \frac{TP}{FP + TP}$
- "recall" $r = \frac{TP}{TP + FN}$
- "f-beta-score" $F_{\beta} = (1+\beta) \frac{pr}{r+\beta p}$

Value

The function show.roc (show.pr) plots the ROC-curve (PR-curve) and returns the device associated with the plotting window.

The function pr returns a (steps x 2) data.frame where steps is the number of thresholds used in the validation process. The first column contains precisions and the second recalls - see details.

The function rates also returns a (steps x 2) data.frame where the first column contains true positive rates and the second column false positive rates - see details.

The function fscores returns steps fscores according to the steps confusion matrices contained in the 'table' argument - see details.
