### 1 Overview

This package implements the Signaling Pathway Impact Analysis (SPIA) algorithm described in Tarca et al. (2009), Khatri et al. (2007) and Draghici et al. (2007). SPIA uses the information from a set of differentially expressed genes and their fold changes, as well as pathways topology in order to assess the significance of the pathways in the condition under the study. The current version of SPIA algorithm uses KEGG signaling pathway data. SPIA ready KEGG pathway data for homo sapiens is included in the package and also available at

http://bioinformaticsprb.med.wayne.edu/SPIA/.

The pathways included for each organism are those containing only directed relations between genes/proteins and no reactions.

## 2 Pathway analysis with SPIA package

This document provides basic introduction on how to use the SPIA package. For extended description of the methods used by this package please consult these references: Tarca et al. (2009); Khatri et al. (2007); Draghici et al. (2007).

We demonstrate the functionality of this package using a colorectal cancer dataset obtained using Affymetrix GeneChip technology and available through GEO (GSE4107). The experiment contains 10 normal samples and 12 colorectal cancer samples and is described by Hong et al. (2007). RMA preprocessing of the raw data was performed using the **affy** package, and a two group moderated t-test was applied using the **limma** package. The data frame obtained as an end result from the function topTable in limma is used as starting point for preparing the input data for SPIA. This data frame called top was made available in the colorectalcancer dataset included in the SPIA package:

> library(SPIA)
> data(colorectalcancer)

For SPIA to work, we need a vector with log2 fold changes between the two groups for all the genes considered to be differentially expressed. The names of this vector must be Entrez gene IDs. The following lines will add one additional column in the top data frame annotating each affymetrix probeset to an Entrez ID. Since there may be several probesets for the same Entrez ID, there are two easy ways to obtain one log fold change per gene. The first option is to use the fold change of the most significant probeset for each gene, while the second option is to average the log fold-changes of all probestes of the same gene. In the example below we used the former approach. The genes in this example are called differentially expressed provided that their FDR p-value is less than 0.05. The following lines start with the top data frame and produce two vectors that are required as input by spia function:

```
> library(hgu133plus2.db)
> x <- hgu133plus2ENTREZID
> top$ENTREZ <- unlist(as.list(x[top$ID]))
> top <- top[!is.na(top$ENTREZ), ]
> top <- top[!duplicated(top$ENTREZ), ]
> tg1 <- top[top$adj.P.Val < 0.05, ]</pre>
```

```
> DE_Colorectal = tg1$logFC
```

```
> names(DE_Colorectal) <- as.vector(tg1$ENTREZ)</pre>
```

```
> ALL_Colorectal = top$ENTREZ
```

The DE\_Colorectal is a vector containing the log2 fold changes of the genes found to be differentially expressed between cancer and normal samples, and ALL\_Colorectal is a vector with the Entrez IDs of all genes profiled on the microarray. The names of the DE\_Colorectal are the Entrez gene IDs corresponding to the computed log fold-changes.

```

                                     "3725"
                                             "23645" "9510"
                                                              "84869" "7432"
[10] "1490"
```

The SPIA algorithm takes as input the two vectors above and produces a table of pathways ranked from the most to the least significant. This can be achieved by calling the **spia** function as follows:

```
> res = spia(de = DE_Colorectal, all = ALL_Colorectal, organism = "hsa",

If the plots argument is set to TRUE in the function call above, a plot like the one shown in Figure 1 is produced for each pathway on which there are differentially expressed genes. These plots are saved in a pdf file in the current directory.

An overall picture of the pathways significance according to both the over-representation evidence and perturbations based evidence can be obtained with the function plotP and shown in Figure 2. In this plot, the horizontal axis represents the p-value (minus log of) corresponding to the probability of obtaining at least the observed number of genes (NDE) on the given pathway just by chance. The vertical axis represents the p-value (minus log of) corresponding to the probability of obtaining the observed total accumulation (tA) or more extreme on the given pathway just by chance. The computation of pPERT is described in Tarca et al. (2009). In Figure 2 each pathway is shown as a bullet point, and those significant at 5% (set by the threshold argument in plotP) after Bonferroni correction are shown in red.

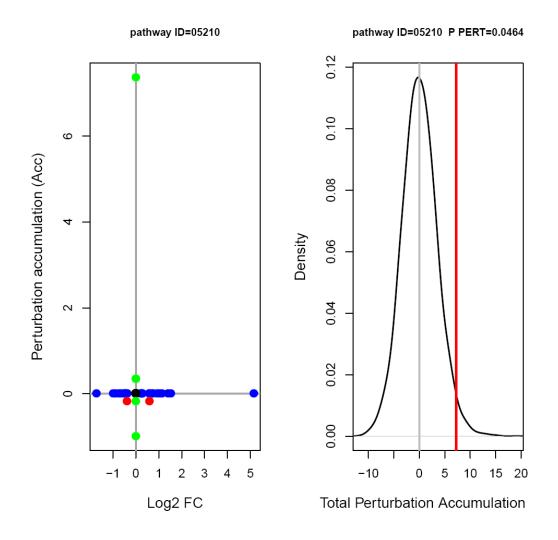

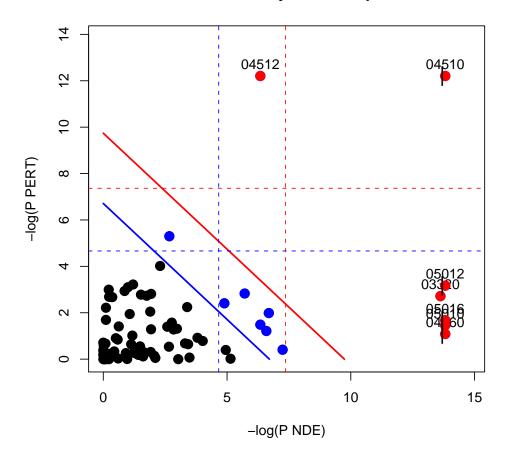

Figure 1: Perturbations plot for colorectal cancer pathway (KEGG ID hsa:05210) using the colorectalcancer dataset. The perturbation of all genes in the pathway are shown as a function of their initial log2 fold changes (left panel). Non DE genes are assigned 0 log2 fold-change. The null distribution of the net accumulated perturbations is also given (right panel). The observed net accumulation tA with the real data is shown as a red vertical line.

> plotP(res, threshold = 0.05)

### SPIA two-way evidence plot

Figure 2: SPIA evidence plot for the colorectal cancer dataset. Each pathway is represented by one dot. The pathways at the right of the red oblique line are significant after Bonferroni correction of the global p-values, pG. The pathways at the right of the blue oblique line are significant after a FDR correction of the global p-values, pG.

SPIA algorithm is illustrated also using the Vessels dataset:

```
> data(Vessels)
> res <- spia(de = DE_Vessels, all = ALL_Vessels, organism = "hsa",</p>
      nB = 500, plots = FALSE, beta = NULL, verbose = FALSE)
+
> res$Name = substr(res$Name, 1, 10)
> res[1:15, -12]
```

The pathway image as provided by KEGG having the differentially expressed genes highlighted in red can be obtained by pasting in a web browser the links available in the KEGGLINK column of the data frame produced by the function spia. For example,

> res[, "KEGGLINK"][20]

#### [1] "http://www.genome.jp/dbget-bin/show\_pathway?hsa05211+7424+6513+112399+5155+3725"

is the link that would display the image of the 20th pathway in the res dataframe above. Note that the results for these datasets my differ from the ones described in Tarca et al. (2009) since a) the pathways database used herein was updated and b) the default beta values were changed. The directed adjacency matrices of the graphs describing the different types of relations between genes/proteins (such as activation or repression) used by SPIA are available in the extdata/hsaSPIA.RData file for the homo sapiens organism. The types of relations considered by SPIA and the default weight (beta coefficient) given to them are:

```
> rel <- c("activation", "compound", "binding/association", "expression",

A 0 value for a given relation type results in discarding those type of relations from the analysis for all pathways. The default values of **beta** can changed by the user at any time by setting the **beta** argument of the **spia** function call.

Other organisms' KEGG pathway data can be downloaded from http://bioinformaticsprb.med. wayne.edu/SPIA as a "[org]SPIA.RData" file and copied into the extdata directory of the SPIA package, and therefore make it available to the function spia.

The user has the ability to generate his own gene/protein relation data and put it in a list format as the one shown in the hsaSPIA.RData file. In this file, each pathway data is included in a list:

```
> load(file = paste(system.file("extdata/hsaSPIA.RData", package = "SPIA")))
> names(path.info[["05210"]])
```

```

5880	0	1	0	0	0	0
5881	0	1	0	0	0	0
332	0	0	0	0	0	0

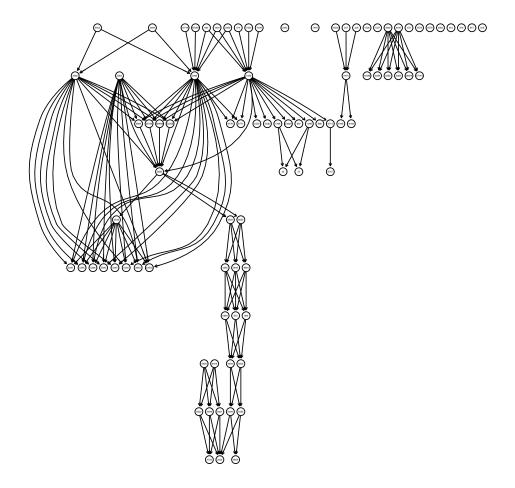

In the matrix above, only 0 and 1 values are allowed. 1 means the gene/protein given by the column has a relation of type "activation" with the gene/protein given by the row of the matrix. Using other R packages such as graph and Rgraphviz one can visualize the richness of gene/protein relations of each type in each pathway. Firstly we load the required packages and create a function that can be used to plot as a graph each type of relation of any pathway, as used by SPIA.

```
> library(graph)
> library(Rgraphviz)
> plotG <- function(B) {</pre>
      nnms <- NULL
+
+
      colls <- NULL
      mynodes <- colnames(B)
+
      L <- list()
+
+
      n < - dim(B)[1]
+
      for (i in 1:n) {
          L[i] <- list(edges = rownames(B)[abs(B[, i]) > 0])
+
           if (sum(B[, i] != 0) > 0) {
+
               nnms <- c(nnms, paste(colnames(B)[i], rownames(B)[B[,
+
                   i] != 0], sep = "~"))
+
          }
+
      }
+
+
      names(L) <- rownames(B)</pre>
+
      g <- new("graphNEL", nodes = mynodes, edgeL = L, edgemode = "directed")
      plot(g)
+
+ }
```

We plot then the "activation" relations in the ErbB signaling pathway, based on the hsaSPIA data. For more details on how to use the main function in this package use "?spia".
