Package 'SpliceWiz'

April 11, 2023

Title Easy, optimized, and accurate alternative splicing analysis in R

Version 1.0.4

Date 2023-03-28

Description Reads and fragments aligned to splice junctions can be used to quantify alternative splicing events (ASE). However, overlapping ASEs can confound their quantification. SpliceWiz quantifies ASEs, calculating percent-spliced-in (PSI) using junction reads, and intron retention using IRFinder-based quantitation. Novel filters identify ASEs that are relatively less confounded by overlapping events, whereby PSIs can be calculated with higher confidence. SpliceWiz is ultra-fast, using multi-threaded processing of BAM files. It can be run using a graphical user or command line interfaces. GUI-based interactive visualization of differential ASEs, including novel group-based RNA-seq coverage visualization, simplifies short-read RNA-seq analysis in R.

`SpliceWiz-package` *SpliceWiz: efficient and precise alternative splicing analysis in R*

Description

SpliceWiz is a computationally efficient and user friendly workflow that analyses aligned short-read RNA sequencing for differential intron retention and alternative splicing.

Details

SpliceWiz uses isoform-specific alignments to quantify percent-spliced-in ratios (i.e. ratio of the "included" isoform, as a proportion of "included" and "excluded" isoforms). For intron retention (IR), the abundance of the intron-retaining transcript (included isoform) is quantified using the trimmed-mean depth of intron coverage with reads, whereas the spliced transcript (excluded isoform) is measured as the splicing of the intron as well as that of overlapping introns (since splicing of any overlapping intron implies the intron of interest is not retained). For other forms of alternative splicing, junction reads (reads aligned across splice junctions) are used to quantify included and excluded isoforms.

SpliceWiz processes BAM files (aligned RNA sequencing) using ompBAM::ompBAM-package. ompBAM is a C++ library that allows R packages (via the Rcpp framework) to efficiently read BAM files using OpenMP-based multi-threading. SpliceWiz processes BAM files via the processBAM function, using a splicing and intron reference built from any given genome / gene annotation resource using the buildRef function. processBAM generates two outputs per BAM file: a `txt.gz` file which is a gzip-compressed text file with multiple tables, containing information including junction read counts and intron retention metrics. This output is very similar to that of IRFinder, as the analysis steps of SpliceWiz's BAM processing was built on an improved version of IRFinder's source code (version 1.3.1). Additionally, processBAM outputs a COV file, which is a binary bgzf-compressed file that contains strand-specific coverage data.

Once individual files have been analysed, SpliceWiz compiles a dataset using these individual outputs, using collateData. This function unifies junctions detected across the dataset, and generates included / excluded counts of all putative IR events and annotated alternative splicing events (ASEs). This dataset is exported as a collection of files including an H5 database. The data is later imported into the R session using the makeSE function, as a NxtSE object.

The NxtSE object is a specialized SummarizedExperiment object tailored for use in SpliceWiz. Annotation of rows provide information about ASEs via rowData, while columns allows users to provide annotations via colData.

SpliceWiz offers several novel filters via the ASEFilter class. See ASEFilter for details.

Once the NxtSE is annotated and filtered, differential analysis is performed, using limma, DESeq2 or DoubleExpSeq wrappers. These wrappers model isoform counts as log-normal, negative-binomial, or beta-binomial distributions, respectively. See ASE-methods for details.

Finally, SpliceWiz provides visualisation tools to illustrate alternative splicing using coverage plots, including a novel method to normalise RNA-seq coverage grouped by experimental condition. This approach accounts for variations introduced by sequenced library size and gene expression. SpliceWiz efficiently computes and visualises means and variations in per-nucleotide coverage depth across alternate exons in genomic loci.

The main functions are:

- Build-Reference-methods - Prepares genome and gene annotation references from FASTA and GTF files and synthesizes the SpliceWiz reference for processing BAM files, collating the NxtSE object.
- STAR-methods - (Optional) Provides wrapper functions to build the STAR genome reference and alignment of short-read FASTQ raw sequencing files. This functionality is only available on systems with STAR installed.
- processBAM - OpenMP/C++ based algorithm to analyse single or multiple BAM files.
- collateData - Collates an experiment based on multiple IRFinder outputs for individual samples, into one unified H5-based data structure.
- makeSE - Constructs a NxtSE (H5-based SummarizedExperiment) object, specialised to house measurements of retained introns and junction counts of alternative splice events.
- applyFilters - Use default or custom filters to remove alternative splicing or IR events pertaining to low-abundance genes and transcripts.
- ASE-methods - one-step method to perform differential alternate splice event (ASE) analysis on a NxtSE object using limma or DESeq2.
- make_plot_data: Functions that compile individual and group-mean percent spliced in (PSI) values of IR and alternative splice events; useful to produce scatter plots or heatmaps.
- plotCoverage: Generate RNA-seq coverage plots of individual samples or across samples grouped by user-specified conditions

See the SpliceWiz Quick-Start for worked examples on how to use SpliceWiz SpliceWiz Cookbook for real-life usage examples

ASE-methods *Differential Alternative Splicing Event analysis*

Description

Use Limma, DESeq2, DoubleExpSeq and satuRn wrapper functions to test for differential Alternative Splice Events (ASEs)

Usage

```
ASE_limma(
  se,
  test_factor,
  test_nom,
  test_denom,
  batch1 = "",
  batch2 = "",
  IRmode = c("all", "annotated", "annotated_binary"),
  filter_antiover = TRUE,
  filter_antinear = FALSE
)

ASE_DESeq(
  se,
  test_factor,
  test_nom,
  test_denom,
  batch1 = "",
  batch2 = "",
  n_threads = 1,
  IRmode = c("all", "annotated", "annotated_binary"),
  filter_antiover = TRUE,
  filter_antinear = FALSE
)

ASE_DoubleExpSeq(
  se,
  test_factor,
  test_nom,
  test_denom,
  IRmode = c("all", "annotated", "annotated_binary"),
  filter_antiover = TRUE,
  filter_antinear = FALSE
)

ASE_satuRn(
  se,
```

```
  test_factor,
  test_nom,
  test_denom,
  batch1 = "",
  batch2 = "",
  n_threads = 1,
  IRmode = c("all", "annotated", "annotated_binary"),
  filter_antiover = TRUE,
  filter_antinear = FALSE,
  filterByMinCPM = 0
)
```

Arguments

`se`	The NxtSE object created by `makeSE()`. To reduce runtime and avoid excessive multiple testing, consider filtering the object using applyFilters
`test_factor`	The condition type which contains the contrasting variable
`test_nom`	The nominator condition to test for differential ASE. Usually the "treatment" condition
`test_denom`	The denominator condition to test against for differential ASE. Usually the "control" condition
`batch1, batch2`	(Optional, limma and DESeq2 only) One or two condition types containing batch information to account for.
`IRmode`	(default `all`) Choose the approach to quantify IR events. Default `all` considers all introns as potentially retained, and calculates IR-ratio based on total splicing across the intron using the "SpliceOver" or "SpliceMax" approach (see collateData). Other options include `annotated` which calculates IR-ratios for annotated introns only, and `annotated_binary` which calculates PSI considering the "included" isoform as the IR-transcript, and the "excluded" transcript is quantified from splice counts only across the exact intron (but not that of overlapping introns). IR-ratio are denoted as "IR" events, whereas PSIs calculated using IR and intron-spliced binary alternatives are denoted as "RI" events.
`filter_antiover, filter_antinear`	Whether to remove novel IR events that overlap over or near anti-sense genes. Default will exclude antiover but not antinear introns. These are ignored if strand-specific RNA-seq protocols are used.
`n_threads`	(DESeq2 only) How many threads to use for DESeq2 based analysis.
`filterByMinCPM`	(default `0`) In `ASE_satuRn()`, Included/Excluded counts will be filtered using this value as the threshold prior to satuRn analysis. Filtering is performed using `edgeR::filterByExpr()` parsing this parameter into its `min.count` parameter.

Details

Using **limma**, SpliceWiz models included and excluded counts as log-normal distributed, whereas using **DESeq2**, SpliceWiz models included and excluded counts as negative binomial distributed with dispersion shrinkage according to their mean count expressions. For **limma** and **DESeq2**,

differential ASE are considered as the "interaction" between included and excluded splice counts for each sample. See this vignette for an explanation of how this is done.

SpliceWiz's **limma** wrapper implements an additional filter where ASEs with an average cpm values of either Included or Excluded counts are less than 1. **DESeq2** has its own method for handling outliers, which seems to work well for handling situations where PSI ~= 0 or PSI ~= 1.

Time series are supported by SpliceWiz to a limited extent. Time series analysis is only performed via DESeq2 (using its "LRT" mode). To activate time series differential analysis, run `ASE_DESeq()` specifying `test_factor` as the column of numeric values containing time series data. The `test_nom` and `test_denom` parameters must be left blank. See example below.

Using **DoubleExpSeq**, included and excluded counts are modeled using the generalized beta prime distribution, using empirical Bayes shrinkage to estimate dispersion.

Using **satuRn**, included and excluded counts are modeled using the quasi-binomial distribution in a generalised linear model.

EventType are as follow:

- `IR` = intron retention (IR-ratio) - all introns are considered
- `MXE` = mutually exclusive exons
- `SE` = skipped exons
- `AFE` = alternate first exon
- `ALE` = alternate last exon
- `A5SS` = alternate 5'-splice site
- `A3SS` = alternate 3'-splice site
- `RI` = (known / annotated) intron retention (PSI).

NB: SpliceWiz measures intron retention events using two different approaches, the choice of which is left to the user - see ASE-methods:

- **IR** (intron retention) events: considers all introns to be potentially retained. Given in most scenarios there may be uncertainty as to which of the many mutually-overlapping introns are spliced to produce the major isoform, SpliceWiz adopts the IRFinder approach by using the IR-ratio. The "included" isoform is the relative abundance of the IR-transcript, as approximated by the trimmed-mean depth of coverage across the intron (excluding outliers including exons of other transcripts, intronic elements such as snoRNAs, etc). The "excluded isoform" includes **all** spliced transcripts that contain an overlapping intron, as estimated via SpliceWiz's `SpliceOver` and IRFinder's `SpliceMax` methods - see collateData.
- **RI** (annotated retained introns) considers only annotated retained introns, i.e., those annotated within the given reference. These are quantified using PSI, considering the included (IR-transcript) and excluded (splicing of the exact intron) as binary alternatives.

SpliceWiz considers "included" counts as those that represent abundance of the "included" isoform, whereas "excluded" counts represent the abundance of the "excluded" isoform. To allow comparison between modalities, SpliceWiz applies a convention whereby the "included" transcript is one where its splice junctions are by definition shorter than those of "excluded" transcripts. Specifically, this means the included / excluded isoforms are as follows:

EventType	Included	Excluded
IR or RI	Intron Retention	Spliced Intron
MXE	Upstream exon inclusion	Downstream exon inclusion
SE	Exon inclusion	Exon skipping
AFE	Downstream exon usage	Upstream exon usage
ALE	Upstream exon usage	Downstream exon usage
A5SS	Downstream 5'-SS	Upstream 5'-SS
A3SS	Upstream 3'-SS	Downstream 3'-SS

Value

For all methods, a data.table containing the following:

- EventName: The name of the ASE event. This identifies each ASE in downstream functions including makeMeanPSI, makeMatrix, and plotCoverage
- EventType: The type of event. See details section above.
- EventRegion: The genomic coordinates the event occupies. This spans the most upstream and most downstream splice junction involved in the ASE, and is use to guide the plotCoverage function.
- flags: Indicates which isoforms are NMD substrates and/or which are formed by novel splicing only.
- AvgPSI_nom, Avg_PSI_denom: the average percent spliced in / percent IR levels for the two conditions being contrasted. `nom` and `denom` in column names are replaced with the condition names. Note this is a geometric mean, based on the arithmetic mean of logit PSI values.
- deltaPSI: The difference in PSI between the mean values of the two conditions.

limma specific output

- logFC, AveExpr, t, P.Value, adj.P.Val, B: limma topTable columns of differential ASE. See limma::topTable for details.
- inc/exc_(logFC, AveExpr, t, P.Value, adj.P.Val, B): limma results for differential testing for raw included / excluded counts only

DESeq2 specific output

- baseMean, log2FoldChange, lfcSE, stat, pvalue, padj: DESeq2 results columns for differential ASE; see DESeq2::results for details.
- inc/exc_(baseMean, log2FoldChange, lfcSE, stat, pvalue, padj): DESeq2 results for differential testing for raw included / excluded counts only

satuRn specific output

- estimates, se, df, t, pval, regular_FDR: estimated log-odds ratio, standard error, degrees of freedom, (Wald) t statistic, nominal p-value and associated false discovery rate
- empirical_pval, empirical_FDR: nominal p value and associated FDR computed by estimating the null distribution of the test statistic empirically (by satuRn).

DoubleExp specific output

- MLE_nom, MLE_denom: Maximum likelihood expectation of PSI values for the denom in column names are replaced with the condition names
- MLE_LFC: Log2-fold change of the MLE
- P.Value, adj.P.Val: Nominal and BH-adjusted P values
- n_eff: Number of effective samples (i.e. non-zero or non-unity PSI)
- mDepth: Mean Depth of splice coverage in each of the two groups.
- Dispersion_Reduced, Dispersion_Full: Dispersion values for reduced and full models. See DoubleExpSeq::DBGLM1 for details.

Functions

- `ASE_limma()`: Use limma to perform differential ASE analysis of a filtered NxtSE object
- `ASE_DESeq()`: Use DESeq2 to perform differential ASE analysis of a filtered NxtSE object
- `ASE_DoubleExpSeq()`: Use DoubleExpSeq to perform differential ASE analysis of a filtered NxtSE object (uses double exponential beta-binomial model) to estimate group dispersions, followed by LRT
- `ASE_satuRn()`: Use satuRn to perform differential ASE analysis of a filtered NxtSE object

```

`ASEFilter-class` *SpliceWiz filters to remove low-confidence alternative splicing and intron retention events*

Description

SpliceWiz implements a number of novel filters designed to exclude alternative splicing events (ASEs) that yield low-confidence estimates.

Usage

```
ASEFilter(
  filterClass = c("Data", "Annotation"),
 filterType = c("Depth", "Participation", "Consistency", "Modality", "Protein_Coding",
    "NMD", "TSL", "Terminus", "ExclusiveMXE"),
  pcTRUE = 100,
  minimum = 20,
  maximum = 1,
  minDepth = 5,
  condition = "",
  minCond = -1,
  EventTypes = c("IR", "MXE", "SE", "A3SS", "A5SS", "AFE", "ALE", "RI")
)
```

Arguments

`filterClass`	Must be either `"Data"` or `"Annotation"`. See details
`filterType`	Must be a valid `"Data"` or `"Annotation"` filter. See details
`pcTRUE`	If conditions are set, what percentage of all samples in each of the condition must satisfy the filter for the event to pass the filter check. Must be between 0 and 100 (default 100)
`minimum`	Filter-dependent argument. See details

maximum	Filter-dependent argument. See details
minDepth	Filter-dependent argument. See details
condition	(default "") If set, must match the name of an experimental condition in the NxtSE object to be filtered, i.e. a column name in colData(se). Leave blank to disable filtering by condition
minCond	(default -1) If condition is set, how many minimum number of conditions must pass the filter criteria. For example, if condition = "Batch", and batches are "A", "B", or "C", setting minCond = 2 with pcTRUE = 100 means that all samples belonging to two of the three types of Batch must pass the filter criteria. Setting -1 means all elements of condition must pass criteria. Set to -1 when the number of elements in the experimental condition is unknown. Ignored if condition is left blank.
EventTypes	What types of events are considered for filtering. Must be one or more of c("IR", "MXE", "SE", "A3SS", "A5SS", "AFE", "ALE", "RI"). Events not specified in EventTypes are not filtered (i.e. they will pass the filter without checks)

Details

Annotation Filters

- **Modality**: Filters for specific modalities of ASEs. All events belonging to the specified EventTypes are removed. No additional parameters required.
- **Protein_Coding**: Filters for alternative splicing or IR events involving protein-coding transcripts. No additional parameters required.
- **NMD**: Filters for events in which one isoform is a predicted NMD substrate.
- **TSL**: filters for events in which both isoforms have a TSL level below or equal to minimum
- **Terminus**: In alternate first exons, the splice junction must not be shared with another transcript for which it is not its first intron. For alternative last exons, the splice junction must not be shared with another transcript for which it is not its last intron
- **ExclusiveMXE**: For MXE events, the two alternate casette exons must not overlap in their genomic regions

Data Filters

- **Depth**: Filters IR or alternative splicing events of transcripts that are "expressed" with adequate Depth as calculated by the sum of all splicing and IR reads spanning the event. Events with Depth below minimum are filtered out
- **Participation**: Participation means different things to IR and alternative splicing.

  For **IR**, Participation refers to the percentage of the measured intron covered with reads. Only introns of samples with a depth of intron coverage above minDepth are assessed, with introns with coverage percentage below minimum are filtered out.

  For **Alternative Splicing**, Participation refers to the percentage of all splicing events observed across the genomic region that is compatible with either the included or excluded event. This prevents SpliceWiz from doing differential analysis between two minor isoforms. Instead of

IntronDepth, in AS events SpliceWiz considers events where the spliced reads from both exonic regions exceed `minDepth`. Then, events with a splicing coverage below `minimum` are excluded.

We recommend testing IR events for > 70% coverage and AS events for > 40% coverage as given in the default filters which can be accessed using getDefaultFilters

- **Consistency**: Skipped exons (SE) and mutually exclusive exons (MXE) comprise reads aligned to two contiguous splice junctions. Most algorithms take the average counts from both junctions. This will inadvertently include transcripts that share one but not both splice events. To check that this is not happening, we require both splice junctions to have comparable counts. This filter checks whether reads from each splice junction comprises a reasonable proportion of the sum of these reads.

  Events are excluded if either of the upstream or downstream event is lower than total splicing events by a log-2 magnitude above `maximum`. For example, if `maximum = 2`, we require both upstream and downstream events to represent at least 1/(2^2) = 1/4 of the sum of upstream and downstream event. If `maximum = 3`, then each junction must be at least 1/8 of total, etc. This is considered for each isoform of each event, as long as the total counts belonging to the considered isoform is above `minDepth`.

  IR-events are also checked. For IR events, the upstream and downstream exon-intron spanning reads must comprise a reasonable proportion of total exon-intron spanning reads.

We highly recommend using the default filters, which can be acquired using getDefaultFilters

Value

An ASEFilter object with the specified parameters

Functions

- `ASEFilter()`: Constructs a ASEFilter object

See Also

Run_SpliceWiz_Filters

Examples

```
# Create a ASEFilter that filters for protein-coding ASE
f1 <- ASEFilter(filterClass = "Annotation", filterType = "Protein_Coding")

# Create a ASEFilter that filters for Depth >= 20 in IR events
f2 <- ASEFilter(
    filterClass = "Data", filterType = "Depth",
    minimum = 20, EventTypes = c("IR", "RI")
)
```

```
# Create a ASEFilter that filters for Participation > 60% in splice events
# that must be satisfied in at least 2 categories of condition "Genotype"
f3 <- ASEFilter(
    filterClass = "Data", filterType = "Participation",
    minimum = 60, EventTypes = c("MXE", "SE", "AFE", "ALE", "A3SS", "A5SS"),
    condition = "Genotype", minCond = 2
)

# Create a ASEFilter that filters for Depth > 10 in all events
# that must be satisfied in at least 50% of each gender
f4 <- ASEFilter(
    filterClass = "Data", filterType = "Depth",
    minimum = 10, condition = "gender", pcTRUE = 50
)

# Get a description of what these filters do:
f1
f2
f3
f4
```

Build-Reference-methods

Builds reference files used by SpliceWiz

Description

These function builds the reference required by the SpliceWiz engine, as well as alternative splicing annotation data for SpliceWiz. See examples below for guides to making the SpliceWiz reference.

Usage

```
getResources(
  reference_path = "./Reference",
  fasta = "",
  gtf = "",
  overwrite = FALSE,
  force_download = FALSE,
  verbose = TRUE
)

buildRef(
  reference_path = "./Reference",
  fasta = "",
  gtf = "",
  overwrite = FALSE,
  force_download = FALSE,
  chromosome_aliases = NULL,
```

```
  genome_type = "",
  nonPolyARef = "",
  MappabilityRef = "",
  BlacklistRef = "",
  useExtendedTranscripts = TRUE,
  lowMemoryMode = TRUE,
  verbose = TRUE
)

buildFullRef(
  reference_path,
  fasta,
  gtf,
  chromosome_aliases = NULL,
  overwrite = FALSE,
  force_download = FALSE,
  genome_type = genome_type,
  use_STAR_mappability = FALSE,
  nonPolyARef = getNonPolyARef(genome_type),
  BlacklistRef = "",
  useExtendedTranscripts = TRUE,
  n_threads = 4
)

getNonPolyARef(genome_type)
```

Arguments

reference_path	(REQUIRED) The directory path to store the generated reference files
fasta	The file path or web link to the user-supplied genome FASTA file. Alternatively, the name of the AnnotationHub record containing the genome resource. May be omitted if `getResources()` has already been run using the same `reference_path`.
gtf	The file path or web link to the user-supplied transcript GTF file (or gzipped GTF file). Alternatively, the name of the AnnotationHub record containing the transcript GTF file. May be omitted if `getResources()` has already been run using the same `reference_path`.
overwrite	(default `FALSE`) For `getResources()`: if the genome FASTA and gene annotation GTF files already exist in the `resource` subdirectory, it will not be overwritten. For `buildRef()` and `buildFullRef()`: the SpliceWiz reference will not be overwritten if one already exist. A reference is considered to exist if the file `SpliceWiz.ref.gz` is present inside `reference_path`.
force_download	(default `FALSE`) When online resources are retrieved, a local copy is stored in the `SpliceWiz` BiocFileCache. Subsequent calls to the web resource will fetch the local copy. Set `force_download` to `TRUE` will force the resource to be downloaded from the web. Set this to `TRUE` only if the web resource has been updated since the last retrieval.
verbose	(default `TRUE`) If `FALSE`, will silence progress messages

`chromosome_aliases`
: (Highly optional) A 2-column data frame containing chromosome name conversions. If this is set, allows processBAM to parse BAM alignments to a genome whose chromosomes are named differently to the reference genome. The most common scenario is where Ensembl genome typically use chromosomes "1", "2", ..., "X", "Y", whereas UCSC/Gencode genome use "chr1", "chr2", ..., "chrX", "chrY". See example below. Refer to `https://github.com/dpryan79/ChromosomeMappings` for a list of chromosome alias resources.

`genome_type`
: Allows `buildRef()` to select default `nonPolyARef` and `MappabilityRef` for selected genomes. Allowed options are: `hg38`, `hg19`, `mm10`, and `mm9`.

`nonPolyARef`
: (Optional) A BED file of regions defining known non-polyadenylated transcripts. This file is used for QC analysis to measure Poly-A enrichment quality of samples. An RDS file (openable using `readRDS()`) of a GRanges object is acceptable. If omitted, and `genome_type` is defined, the default for the specified genome will be used.

`MappabilityRef`
: (Optional) A BED file of low mappability regions due to repeat elements in the genome. If omitted, the file generated by `calculateMappability()` will be used where available, and if this is not, the default file for the specified `genome_type` will be used. If `genome_type` is not specified, `MappabilityRef` is not used. An RDS file (openable using `readRDS()`) of a GRanges object is acceptable. See details.

`BlacklistRef`
: A BED file of regions to be otherwise excluded from IR analysis. If omitted, a blacklist is not used (this is the default). An RDS file (openable using `readRDS()`) of a GRanges object is acceptable.

`useExtendedTranscripts`
: (default `TRUE`) Should non-protein-coding transcripts such as anti-sense and lincRNA transcripts be included in searching for IR / AS events? Setting `FALSE` (vanilla IRFinder) will exclude transcripts other than `protein_coding` and `processed_transcript` transcripts from IR analysis.

`lowMemoryMode`
: (default `TRUE`) By default, SpliceWiz converts FASTA files to TwoBit, then uses the TwoBit file to fetch genome sequences. In most cases, this method uses less memory and is faster, but can be very slow on some systems. Set this option to `FALSE` (which will convert the TwoBit file back to FASTA) if you experience very slow genome fetching (e.g. when annotating splice motifs).

`use_STAR_mappability`
: (default FALSE) In `buildFullRef()`, whether to run STAR_mappability to calculate low-mappability regions. We recommend setting this to `FALSE` for the common genomes (human and mouse), and to `TRUE` for genomes not supported by `genome_type`. When set to false, the MappabilityExclusion default file corresponding to `genome_type` will automatically be used.

`n_threads`
: The number of threads used to generate the STAR reference and mappability calculations. Multi-threading is not used for SpliceWiz reference generation (but multiple cores are utilised in data-table and fst file processing automatically, where available). See STAR-methods

Details

`getResources()` processes the files, downloads resources from web links or from `AnnotationHub()`,

and saves a local copy in the "resource" subdirectory within the given `reference_path`. Resources are retrieved via either:

1. User-supplied FASTA and GTF file. This can be a file path, or a web link (e.g. 'http://', 'https://' or 'ftp://'). Use `fasta` and `gtf` to specify the files or web paths to use.
2. AnnotationHub genome and gene annotation (Ensembl): supply the names of the genome sequence and gene annotations to `fasta` and `gtf`.

`buildRef()` will first run `getResources()` if resources are not yet saved locally (i.e. `getResources()` is not already run). Then, it creates the SpliceWiz references. Typical run-times are 5 to 10 minutes for human and mouse genomes (after resources are downloaded).

NB: the parameters `fasta` and `gtf` can be omitted in `buildRef()` if `getResources()` is already run.

`buildFullRef()` builds the STAR aligner reference alongside the SpliceWiz reference. The STAR reference will be located in the `STAR` subdirectory of the specified reference path. If `use_STAR_mappability` is set to `TRUE` this function will empirically compute regions of low mappability. This function requires `STAR` to be installed on the system (which only runs on linux-based systems).

`getNonPolyARef()` returns the path of the non-polyA reference file for the human and mouse genomes.

Typical usage involves running `buildRef()` for human and mouse genomes and specifying the `genome_type` to use the default `MappabilityRef` and `nonPolyARef` files for the specified genome. For non-human non-mouse genomes, use one of the following alternatives:

- Create the SpliceWiz reference without using Mappability Exclusion regions. To do this, simply run `buildRef()` and omit `MappabilityRef`. This is acceptable assuming the introns assessed are short and do not contain intronic repeats
- Calculating Mappability Exclusion regions using the STAR aligner, and building the SpliceWiz reference. This can be done using the `buildFullRef()` function, on systems where `STAR` is installed
- Instead of using the STAR aligner, any genome splice-aware aligner could be used. See Mappability-methods for an example workflow using the Rsubread aligner. After producing the `MappabilityExclusion.bed.gz` file (in the `Mappability` subfolder), run `buildRef()` using this file (or simply leave it blank).

BED files are tab-separated text files containing 3 unnamed columns specifying chromosome, start and end coordinates. To view an example BED file, open the file specified in the path returned by `getNonPolyARef("hg38")`

See examples below for common use cases.

Value

For `getResources`: creates the following local resources:

- `reference_path/resource/genome.2bit`: Local copy of the genome sequences as a TwoBitFile.
- `reference_path/resource/transcripts.gtf.gz`: Local copy of the gene annotation as a gzip-compressed file.

For `buildRef()` and `buildFullRef()`: creates a SpliceWiz reference which is written to the given directory specified by `reference_path`. Files created includes:

- `reference_path/settings.Rds`: An RDS file containing parameters used to generate the SpliceWiz reference
- `reference_path/SpliceWiz.ref.gz`: A gzipped text file containing collated SpliceWiz reference files. This file is used by processBAM
- `reference_path/fst/`: Contains fst files for subsequent easy access to SpliceWiz generated references
- `reference_path/cov_data.Rds`: An RDS file containing data required to visualise genome / transcript tracks.

`buildFullRef()` also creates a `STAR` reference located in the `STAR` subdirectory inside the designated `reference_path`

For `getNonPolyARef()`: Returns the file path to the BED file for the nonPolyA loci for the specified genome.

Functions

- `getResources()`: Processes / downloads a copy of the genome and gene annotations and stores this in the "resource" subdirectory of the given reference path
- `buildRef()`: First calls `getResources()` (if required). Afterwards creates the SpliceWiz reference in the given reference path
- `buildFullRef()`: One-step function that fetches resources, creates a STAR reference (including mappability calculations), then creates the SpliceWiz reference
- `getNonPolyARef()`: Returns the path to the BED file containing coordinates of known non-polyadenylated transcripts for genomes `hg38`, `hg19`, `mm10` and `mm9`,

    genome_type = ""
)
```

```
## End(Not run)
```

---

collateData *Collates a dataset from (processBAM) output files of individual samples*

Description

`collateData()` creates a dataset from a collection of processBAM output files belonging to an experiment.

Usage

```
collateData(
  Experiment,
  reference_path,
  output_path,
  IRMode = c("SpliceOver", "SpliceMax"),
  novelSplicing = FALSE,
  forceStrandAgnostic = FALSE,
  novelSplicing_minSamples = 3,
  novelSplicing_countThreshold = 10,
  novelSplicing_minSamplesAboveThreshold = 1,
  novelSplicing_requireOneAnnotatedSJ = TRUE,
  overwrite = FALSE,
  n_threads = 1,
  lowMemoryMode = TRUE
)
```

Arguments

`Experiment`	(Required) A 2 or 3 column data frame, ideally generated by findSpliceWizOutput or findSamples. The first column designate the sample names, and the 2nd column contains the path to the processBAM output file (of type `sample.txt.gz`). (Optionally) a 3rd column contains the coverage files (of type `sample.cov`) of the corresponding samples. NB: all other columns are ignored.
`reference_path`	(Required) The path to the reference generated by Build-Reference-methods
`output_path`	(Required) The path to contain the output files for the collated dataset
`IRMode`	(default `SpliceOver`) The algorithm to calculate 'splice abundance' in IR quantification. Valid options are `SpliceOver` and `SpliceMax`. See details
`novelSplicing`	(default FALSE) Whether collateData will use novel junction reads detected in samples to infer novel splice variants. All tandem split reads (those bridging two consecutive splice junctions) are used, as well as novel split reads that satisfy abundance criteria (see `novelSplicing_minSamples`, `novelSplicing_minSamplesAboveThreshold`, and `novelSplicing_countThreshold`) are used to synthesise a dataset-specific SpliceWiz reference. See details.

forceStrandAgnostic
: (default FALSE) In poorly-prepared stranded libraries, it may be better to quantify in unstranded mode. Set this to TRUE if your stranded libraries may be contaminated with unstranded reads

novelSplicing_minSamples
: (default 3) Novel junctions are included in building of novel reference if number samples with non-zero counts exceeds this number.

novelSplicing_countThreshold
: (default 10) Threshold of split-reads across novel junctions; used in conjunction with novelSplicing_minSamplesAboveThreshold

novelSplicing_minSamplesAboveThreshold
: (default 1) Novel junctions are included in building of novel reference if novel junction reads are above a pre-defined threshold exceeds this number

novelSplicing_requireOneAnnotatedSJ
: (default TRUE) The default requires novel junctions to have one annotated splice site. If this is disabled, collateData will include novel junctions where neither splice site is annotated.

overwrite
: (default FALSE) If collateData() has previously been run using the same set of samples, it will not be overwritten unless this is set to TRUE.

n_threads
: (default 1) The number of threads to use. If you run out of memory, try lowering the number of threads

lowMemoryMode
: (default TRUE) collateData() will perform optimizations to conserve memory if this is set to TRUE. Otherwise, will prioritise performance.

Details

All sample processBAM outputs must be generated using the same reference.

The combination of junction counts and IR quantification from processBAM is used to calculate percentage spliced in (PSI) of alternative splice events, and intron retention ratios (IR-ratio) of retained introns. Also, QC information is collated. Data is organised in a H5file and FST files for memory and processor efficient downstream access using makeSE.

The original IRFinder algorithm, see the following wiki, uses SpliceMax to estimate abundance of spliced transcripts. This calculates the number of mapped splice events that share the boundary coordinate of either the left or right flanking exon SpliceLeft,SpliceRight, estimating splice abundance as the larger of the two values.

SpliceWiz proposes a new algorithm, SpliceOver, to account for the possibility that the major isoform shares neither boundary, but arises from either of the flanking exon clusters. Exon clusters are contiguous regions covered by exons from any transcript (except those designated as retained_intron or sense_intronic), and are separated by obligate intronic regions (genomic regions that are introns for all transcripts). For introns that are internal to a single exon cluster (i.e. akin to "known-exon" introns from IRFinder), SpliceOver uses GenomicRanges::findOverlaps to sum all splice reads that overlap the same genomic region as the intron of interest.

Detection of novel ASEs: When novelSplicing is set to TRUE, novel junctions (split reads across unannotated junctions from samples of the dataset being collated) are used in conjunction with the reference to compile a list of novel ASEs. To avoid being overwhelmed by a large number of false

positive novel junctions (often due to mis-alignments), a simple filtering strategy is used. This involves including novel junctions only if it occurs in a minimum number of samples (default 3), or if the number of split reads of a novel junction is above a pre-defined threshold (default 10) in a certain number of samples (default 1). These parameters can be set using `novelSplicing_minSamples`, `novelSplicing_countThreshold` and `novelSplicing_minSamplesAboveThreshold` respectively.

Value

`collateData()` writes to the directory given by `output_path`. This output directory is portable (i.e. it can be moved to a different location after running `collateData()` before running makeSE), but individual files within the output folder should not be moved.

Also, the processBAM and collateData output folders should be copied to the same destination and their relative paths preserved. Otherwise, the locations of the "COV" files will not be recorded in the collated data and will have to be re-assigned using `covfile(se)<-`. See makeSE

)

bams <- SpliceWiz_example_bams()
processBAM(bams$path, bams$sample,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "SpliceWiz_Output")
)

expr <- findSpliceWizOutput(file.path(tempdir(), "SpliceWiz_Output"))
collateData(expr,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "Collated_output")
)
```

---

coord2GR *Converts genomic coordinates into a GRanges object*

Description

This function takes a string vector of genomic coordinates and converts it into a GRanges object.

Usage

```
coord2GR(coordinates)
```

Arguments

coordinates	A string vector of one or more genomic coordinates to be converted

Details

Genomic coordinates can take one of the following syntax:

- seqnames:start
- seqnames:start-end
- seqnames:start-end/strand

The following examples are considered valid genomic coordinates:

- "chr1:21535"
- "chr3:10550-10730"
- "X:51231-51330/-"
- "chrM:2134-5232/+"

Value

A GRanges object that corresponds to the given coordinates

Examples

```
se <- SpliceWiz_example_NxtSE()

coordinates <- rowData(se)$EventRegion

gr <- coord2GR(coordinates)
```

Coverage *Calls SpliceWiz's C++ function to retrieve coverage from a COV file*

Description

This function returns an RLE / RLEList or data.frame containing coverage data from the given COV file

COV files are generated by SpliceWiz's processBAM and BAM2COV functions. It records alignment coverage for each nucleotide in the given BAM file. It stores this data in "COV" format, which is an indexed BGZF-compressed format specialised for the storage of unstranded and stranded alignment coverage in RNA sequencing.

Unlike BigWig files, COV files store coverage for both positive and negative strands.

These functions retrieves coverage data from the specified COV file. They are computationally efficient as they utilise random-access to rapidly search for the requested data from the COV file.

Usage

```
getCoverage(file, seqname = "", start = 0, end = 0, strand = c("*", "+", "-"))

getCoverage_DF(
  file,
  seqname = "",
  start = 0,
  end = 0,
  strand = c("*", "+", "-")
)

getCoverageRegions(
  file,
  regions,
  strandMode = c("unstranded", "forward", "reverse")
)

getCoverageBins(
  file,
  region,
  bins = 2000,
  strandMode = c("unstranded", "forward", "reverse"),
  bin_size
)
```

Arguments

`file`	(Required) The file name of the COV file
`seqname`	(Required for `getCoverage_DF`) A string denoting the chromosome name. If left blank in `getCoverage`, retrieves RLEList containing coverage of the entire file.
`start, end`	1-based genomic coordinates. If `start = 0` and `end = 0`, will retrieve RLE of specified chromosome.
`strand`	Either "*", "+", or "-"
`regions`	A GRanges object for a set of regions to obtain mean / total coverage from the given COV file.
`strandMode`	The stranded-ness of the RNA-seq experiment. "unstranded" means that an unstranded protocol was used. Stranded protocols can be either "forward", where the first read is the same strand as the expressed transcript, or "reverse" where the second strand is the same strand as the expressed transcript.
`region`	In `getCoverageBins`, a single query region as a GRanges object
`bins`	In `getCoverageBins`, the number of bins to divide the given `region`. If `bin_size` is given, overrides this parameter
`bin_size`	In `getCoverageBins`, the number of nucleotides per bin

Value

For `getCoverage`: If seqname is left as "", returns an RLEList of the whole BAM file, with each RLE in the list containing coverage data for one chromosome. Otherwise, returns an RLE containing coverage data for the requested genomic region

For `getCoverage_DF`: Returns a two-column data frame, with the first column `coordinate` denoting genomic coordinate, and the second column `value` containing the coverage depth for each coordinate nucleotide.

For `getCoverageRegions`: Returns a GRanges object with an extra metacolumn: `cov_mean`, which gives the mean coverage of each of the given ranges.

For `getCoverageBins`: Returns a GRanges object which spans the given `region`, divided by the number of `bins` or by width as given by `bin_size`. Mean coverage in each bin is calculated (returned by the `cov_mean` metadata column). This function is useful for retrieving coverage of a large region for visualisation, especially when the size of the region vastly exceeds the width of the figure.

Functions

- `getCoverage()`: Retrieves alignment coverage as an RLE or RLElist
- `getCoverage_DF()`: Retrieves alignment coverage as a data.frame
- `getCoverageRegions()`: Retrieves total and mean coverage of a GRanges object from a COV file
- `getCoverageBins()`: Retrieves coverage of a single region from a COV file, binned by the given number of bins or bin_size

Examples

```
se <- SpliceWiz_example_NxtSE()

cov_file <- covfile(se)[1]

# Retrieve Coverage as RLE

cov <- getCoverage(cov_file, seqname = "chrZ",
  start = 10000, end = 20000,
  strand = "*"
)

# Retrieve Coverage as data.frame

cov.df <- getCoverage_DF(cov_file, seqname = "chrZ",
  start = 10000, end = 20000,
  strand = "*"
)

# Retrieve mean coverage of 100-nt window regions as defined
# in a GRanges object:

gr <- GenomicRanges::GRanges(
    seqnames = "chrZ",
```

```
    ranges = IRanges::IRanges(
        start = seq(1, 99901, by = 100),
        end = seq(100, 100000, by = 100)
    ), strand = "-"
)

gr.unstranded <- getCoverageRegions(cov_file,
    regions = gr,
    strandMode = "unstranded"
)

gr.stranded <- getCoverageRegions(cov_file,
    regions = gr,
    strandMode = "reverse"
)

# Retrieve binned coverage of a large region

gr.fetch <- getCoverageBins(
    cov_file,
    region = GenomicRanges::GRanges(seqnames = "chrZ",
        ranges = IRanges::IRanges(start = 100, end = 100000),
        strand = "*"
    ),
    bins = 2000
)

# Plot coverage using ggplot:

require(ggplot2)

ggplot(cov.df, aes(x = coordinate, y = value)) +
    geom_line() + theme_white

ggplot(as.data.frame(gr.unstranded),
    aes(x = (start + end) / 2, y = cov_mean)) +
    geom_line() + theme_white

ggplot(as.data.frame(gr.fetch),
    aes(x = (start + end)/2, y = cov_mean)) +
    geom_line() + theme_white

# Export COV data as BigWig

cov_whole <- getCoverage(cov_file)
bw_file <- file.path(tempdir(), "sample.bw")
rtracklayer::export(cov_whole, bw_file, "bw")
```

---

example-SpliceWiz-data

SpliceWiz Example BAMs and NxtSE Experiment Object

Description

`SpliceWiz_example_bams()` is a wrapper function to obtain and make a local copy of 6 example files provided by the NxtIRFdata companion package to demonstrate the use of SpliceWiz. See NxtIRFdata::example_bams for a description of the provided BAM files.

`SpliceWiz_example_NxtSE()` retrieves a ready-made functioning NxtSE object. The steps to reproduce this object is shown in the example code in makeSE

Usage

```
SpliceWiz_example_bams()

SpliceWiz_example_NxtSE(novelSplicing = FALSE)
```

Arguments

`novelSplicing`	Whether to import an example NxtSE with novel splice event discovery.

Value

In `SpliceWiz_example_bams()`: returns a 2-column data frame containing sample names and BAM paths of the example dataset.

In `SpliceWiz_example_NxtSE()`: returns a NxtSE object.

Functions

- `SpliceWiz_example_bams()`: Returns a 2-column data frame, containing sample names and sample paths (in tempdir()) of example BAM files
- `SpliceWiz_example_NxtSE()`: Returns a (in-memory / realized) NxtSE object that was pre-generated using the SpliceWiz example reference and example BAM files

References

Generation of the mappability files was performed using SpliceWiz using a method analogous to that described in:

Middleton R, Gao D, Thomas A, Singh B, Au A, Wong JJ, Bomane A, Cosson B, Eyras E, Rasko JE, Ritchie W. IRFinder: assessing the impact of intron retention on mammalian gene expression. Genome Biol. 2017 Mar 15;18(1):51. doi:10.1186/s1305901711844

makeSE

Examples

```
# returns a data frame with the first column as sample names, and the
# second column as BAM paths

SpliceWiz_example_bams()
```

```
# Returns a NxtSE object created by the example bams aligned to the
# mock NxtSE reference

se <- SpliceWiz_example_NxtSE()
```

`findSamples` *Convenience Function to (recursively) find all files in a folder.*

Description

Often, files e.g. raw sequencing FASTQ files, alignment BAM files, or processBAM output files, are stored in a single folder under some directory structure. They can be grouped by being in common directory or having common names. Often, their sample names can be gleaned by these common names or the names of the folders in which they are contained. This function (recursively) finds all files and extracts sample names assuming either the files are named by sample names (`level = 0`), or that their names can be derived from the parent folder (`level = 1`). Higher `level` also work (e.g. `level = 2`) mean the parent folder of the parent folder of the file is named by sample names. See details section below.

Usage

```
findSamples(sample_path, suffix = ".txt.gz", level = 0)

findFASTQ(
  sample_path,
  paired = TRUE,
  fastq_suffix = c(".fastq", ".fq", ".fastq.gz", ".fq.gz"),
  level = 0
)

findBAMS(sample_path, level = 0)

findSpliceWizOutput(sample_path, level = 0)
```

Arguments

`sample_path`	The path in which to recursively search for files that match the given `suffix`
`suffix`	A vector of or or more strings that specifies the file suffix (e.g. '.bam' denotes BAM files, whereas ".txt.gz" denotes gzipped txt files).
`level`	Whether sample names can be found in the file names themselves (level = 0), or their parent directory (level = 1). Potentially parent of parent directory (level = 2). Support max level <= 3 (for sanity).
`paired`	Whether to expect single FASTQ files (of the format "sample.fastq"), or paired files (of the format "sample_1.fastq", "sample_2.fastq")
`fastq_suffix`	The name of the FASTQ suffix. Options are: ".fastq", ".fastq.gz", ".fq", or ".fq.gz"

Details

Paired FASTQ files are assumed to be named using the suffix _1 and _2 after their common names; e.g. sample_1.fastq, sample_2.fastq. Alternate FASTQ suffixes for findFASTQ() include ".fq", ".fastq.gz", and ".fq.gz".

In BAM files, often the parent directory denotes their sample names. In this case, use level = 1 to automatically annotate the sample names using findBAMS().

processBAM outputs two files per BAM processed. These are named by the given sample names. The text output is named "sample1.txt.gz", and the COV file is named "sample1.cov", where sample1 is the name of the sample. These files can be organised / tabulated using the function findSpliceWizOutput. The generic function findSamples will organise the processBAM text output files but exclude the COV files. Use the latter as the Experiment in collateData if one decides to collate an experiment without linked COV files, for portability reasons.

Value

A multi-column data frame with the first column containing the sample name, and subsequent columns being the file paths with suffix as determined by suffix.

Functions

- findSamples(): Finds all files with the given suffix pattern. Annotates sample names based on file or parent folder names.
- findFASTQ(): Use findSamples() to return all FASTQ files in a given folder
- findBAMS(): Use findSamples() to return all BAM files in a given folder
- findSpliceWizOutput(): Use findSamples() to return all processBAM output files in a given folder, including COV files

Examples

```
# Retrieve all BAM files in a given folder, named by sample names
bam_path <- tempdir()
example_bams(path = bam_path)
df.bams <- findSamples(sample_path = bam_path,
  suffix = ".bam", level = 0)
# equivalent to:
df.bams <- findBAMS(bam_path, level = 0)

# Retrieve all processBAM() output files in a given folder,
# named by sample names

expr <- findSpliceWizOutput(file.path(tempdir(), "SpliceWiz_Output"))
## Not run:

# Find FASTQ files in a directory, named by sample names
# where files are in the form:
# - "./sample_folder/sample1.fastq"
# - "./sample_folder/sample2.fastq"

findFASTQ("./sample_folder", paired = FALSE, fastq_suffix = ".fastq")
```

```
# Find paired gzipped FASTQ files in a directory, named by parent directory
# where files are in the form:
# - "./sample_folder/sample1/raw_1.fq.gz"
# - "./sample_folder/sample1/raw_2.fq.gz"
# - "./sample_folder/sample2/raw_1.fq.gz"
# - "./sample_folder/sample2/raw_2.fq.gz"

findFASTQ("./sample_folder", paired = TRUE, fastq_suffix = ".fq.gz")

## End(Not run)
```

`Graphics-User-Interface` *Launches the SpliceWiz Graphics User Interface (GUI) using Shiny Dashboard*

Description

This function launches the SpliceWiz interactive app using Shiny Dashboard This is (by default) a dialog window within the RStudio application with the resolution specified by the `res` parameter. Alternatively, setting `mode = "browser"` will launch a resizable browser window (using the default internet browser). The demo mode can be launched by setting `demo = TRUE`. See the SpliceWiz Quick-Start for a guide to using the SpliceWiz GUI.

Usage

```
spliceWiz(
  mode = c("dialog", "browser"),
  res = c("1080p", "720p", "960p", "1440p"),
  demo = FALSE
)
```

Arguments

`mode`	(default `"dialog"`) `"dialog"` displays SpliceWiz in a dialog box with specified width and height. `"browser"` opens SpliceWiz in a browser-like resizable window.
`res`	(default "1080p") Sets width and height of the app to pre-defined dimensions. Possible options are "720p, "960p", "1080p", "1440p", which specifies the height of the app. All are displayed in aspect ratio 16x9
`demo`	(default FALSE) If set to `TRUE`, SpliceWiz will place demo reference and BAM files into the temporary directory.

Value

Runs an interactive shinydashboard SpliceWiz app with the specified mode.

Functions

- `spliceWiz()`: Launches the SpliceWiz GUI

Examples

```
if(interactive()) {

# Launches interactive ShinyDashboard SpliceWiz app as fixed-size dialog box
# 1080p = 1920 x 1080 pixels
    spliceWiz(mode = "dialog", res = "1080p")

# Launches interactive ShinyDashboard SpliceWiz app as browser window
    spliceWiz(mode = "browser")

}
```

`isCOV` *Validates the given file as a valid COV file*

Description

This function takes the path of a possible COV file and checks whether its format complies with that of the COV format defined by this package.

Usage

```
isCOV(coverage_files)
```

Arguments

`coverage_files`	A vector containing the file names of files to be checked

Details

COV files are BGZF-compressed files. The first 4 bytes of the file must always be 'COV\1', distinguishing it from BAM or other files in BGZF format. This function checks whether the given file complies with this.

Value

`TRUE` if all files are valid COV files. `FALSE` otherwise

See Also

processBAM collateData

Examples

```
se <- SpliceWiz_example_NxtSE()

cov_files <- covfile(se)

isCOV(cov_files) # returns true if these are true COV files
```

---

makeSE *Imports a collated dataset into the R session as an NxtSE object*

Description

Creates a NxtSE object from the data (that was collated using collateData). This object is used for downstream differential analysis of IR and alternative splicing events using ASE-methods, data generation for visualization of scatter plots and heatmaps via make_plot_data methods, and coverage visualisation using plotCoverage

Usage

```
makeSE(collate_path, colData, RemoveOverlapping = TRUE, realize = FALSE)
```

Arguments

collate_path	(Required) The output path of collateData pointing to the collated data
colData	(Optional) A data frame containing the sample annotation information. The first column must contain the sample names. Omit colData to generate a NxtSE object of the whole dataset without any assigned annotations. Alternatively, if the names of only a subset of samples are given, then makeSE() will construct the NxtSE object based only on the samples given. The colData can be set later using colData
RemoveOverlapping	(default = TRUE) Whether to filter out overlapping novel IR events belonging to minor isoforms. See details.
realize	(default = FALSE) Whether to load all assay data into memory. See details

Details

makeSE retrieves the data collated by collateData, and initialises a NxtSE object. It references the required on-disk assay data using DelayedArrays, thereby utilising 'on-disk' memory to conserve memory usage.

For extremely large datasets, loading the entire data into memory may consume too much memory. In such cases, make a subset of the NxtSE object (e.g. subset by samples) before loading the data into memory (RAM) using realize_NxtSE. Alternatively supply a data frame to the colData parameter of the makeSE() function. Only samples listed in the first column of the colData data frame will be imported into the NxtSE object.

It should be noted that downstream applications of SpliceWiz, including ASE-methods, plotCoverage, are much faster if the NxtSE is realized. It is recommended to realize the NxtSE object before extensive usage.

If COV files assigned via collateData have been moved relative to the `collate_path`, the created NxtSE object will not be linked to any COV files and plotCoverage cannot be used. To reassign these files, a vector of file paths corresponding to all the COV files of the data set can be assigned using `covfile(se) <- vector_of_cov_files`. See the example below for details.

If `RemoveOverlapping = TRUE`, `makeSE` will try to identify which introns belong to major isoforms, then remove introns of minor introns that overlaps those of major isoforms. Non-overlapping introns are then reassessed iteratively, until all introns are included or excluded in this way. This is important to ensure that overlapping novel IR events are not 'double-counted'.

Value

A NxtSE object containing the compiled data in DelayedArrays (or as matrices if `realize = TRUE`), pointing to the assay data contained in the given `collate_path`

Examples

```
# The following code can be used to reproduce the NxtSE object
# that can be fetched with SpliceWiz_example_NxtSE()

buildRef(
    reference_path = file.path(tempdir(), "Reference"),
    fasta = chrZ_genome(),
    gtf = chrZ_gtf()
)

bams <- SpliceWiz_example_bams()
processBAM(bams$path, bams$sample,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "SpliceWiz_Output")
)

expr <- findSpliceWizOutput(file.path(tempdir(), "SpliceWiz_Output"))
collateData(expr,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "Collated_output")
)

se <- makeSE(collate_path = file.path(tempdir(), "Collated_output"))

# "Realize" NxtSE object to load all H5 assays into memory:

se <- realize_NxtSE(se)

# If COV files have been removed since the last call to collateData()
# reassign them to the NxtSE object, for example:

covfile_path <- system.file("extdata", package = "SpliceWiz")
covfile_df <- findSamples(covfile_path, ".cov")
```

```
covfile(se) <- covfile_df$path
```

`make_plot_data` *Construct data of percent-spliced-in (PSI) matrices and group-average PSIs*

Description

`makeMatrix()` constructs a matrix of PSI values of the given alternative splicing events (ASEs).

`makeMeanPSI()` constructs a table of "average" PSI values, with samples grouped by a number of given conditions (e.g. "group A" and "group B") of a given condition category (e.g. condition "treatment"). See details below.

Usage

```
makeMatrix(
  se,
  event_list,
  sample_list = colnames(se),
  method = c("PSI", "logit", "Z-score"),
  depth_threshold = 10,
  logit_max = 5,
  na.percent.max = 0.1
)

makeMeanPSI(
  se,
  event_list = rownames(se),
  condition,
  conditionList,
  depth_threshold = 10,
  logit_max = 10
)
```

Arguments

`se`	(Required) A NxtSE object generated by makeSE
`event_list`	A character vector containing the names of ASE events (as given by the `EventName` column of differential ASE results table generated by one of the ASE-methods, or the rownames of the NxtSE object)
`sample_list`	(default = `colnames(se)`) In `makeMatrix()`, a list of sample names in the given experiment to be included in the returned matrix

method	In makeMatrix(), rhe values to be returned (default = "PSI"). It can alternately be "logit" which returns logit-transformed PSI values, or "Z-score" which returns Z-score-transformed PSI values
depth_threshold	(default = 10) Samples with the number of reads supporting either included or excluded isoforms below this values are excluded
logit_max	PSI values close to 0 or 1 are rounded up/down to plogis(-logit_max) and plogis(logit_max), respectively. See details.
na.percent.max	(default = 0.1) The maximum proportion of values in the given dataset that were transformed to NA because of low splicing depth. ASE events where there are a higher proportion (default 10%) NA values will be excluded from the final matrix. Most heatmap functions will spring an error if there are too many NA values in any given row. This option caps the number of NA values to avoid returning this error.
condition	The name of the column containing the condition values in colData(se)
conditionList	A list (or vector) of condition values of which to calculate mean PSIs

Details

Note that this function takes the geometric mean of PSI, by first converting all values to logit(PSI), taking the average logit(PSI) values of each condition, and then converting back to PSI using inverse logit.

Samples with low splicing coverage (either due to insufficient sequencing depth or low gene expression) are excluded from calculation of mean PSIs. The threshold can be set using depth_threshold. Excluding these samples is appropriate because the uncertainty of PSI is high when the total included / excluded count is low. Note that events where all samples in a condition is excluded will return a value of NaN.

Using logit-transformed PSI values is appropriate because PSI values are bound to the (0,1) interval, and are often thought to be beta-distributed. The link function often used with beta-distributed models is the logit function, which is defined as logit(x) = function(x) log(x / (1 - x)), and is equivalent to stats::qlogis. Its inverse is equivalent to stats::plogis.

Users wishing to calculate arithmetic means of PSI are advised to use makeMatrix, followed by rowMeans on subsetted sample columns.

Value

For makeMatrix: A matrix of PSI (or alternate) values, with columns as samples and rows as ASE events.

For makeMeanPSI: A 3 column data frame, with the first column containing event_list list of ASE events, and the last 2 columns containing the average PSI values of the nominator and denominator conditions.

Functions

- makeMatrix(): constructs a matrix of PSI values of the given alternative splicing events (ASEs)
- makeMeanPSI(): constructs a table of "average" PSI values

Examples

```
se <- SpliceWiz_example_NxtSE()

colData(se)$treatment <- rep(c("A", "B"), each = 3)

event_list <- rowData(se)$EventName

mat <- makeMatrix(se, event_list[1:10])

diag_values <- makeMeanPSI(se, event_list,
  condition = "treatment",
  conditionList = list("A", "B")
)
```

Mappability-methods *Calculate low mappability genomic regions*

Description

These functions empirically calculate low-mappability (Mappability Exclusion) regions using the given reference. A splice-aware alignment software capable of aligning reads to the genome is required. See details and examples below.

Usage

```
generateSyntheticReads(
  reference_path,
  read_len = 70,
  read_stride = 10,
  error_pos = 35,
  verbose = TRUE,
  alt_fasta_file
)

calculateMappability(
  reference_path,
  aligned_bam = file.path(reference_path, "Mappability", "Aligned.out.bam"),
  threshold = 4,
  n_threads = 1
)
```

Arguments

reference_path	The directory of the reference prepared by getResources
read_len	The nucleotide length of the synthetic reads
read_stride	The nucleotide distance between adjacent synthetic reads

error_pos	The position of the procedurally-generated nucleotide error from the start of each synthetic reads
verbose	Whether additional status messages are shown
alt_fasta_file	(Optional) The path to the user-supplied genome fasta file, if different to that found inside the resource subdirectory of the reference_path. If getResources has already been run, this parameter should be omitted.
aligned_bam	The BAM file of alignment of the synthetic reads generated by generateSyntheticReads(). Users should use a genome splice-aware aligner, preferably the same aligner used to align the samples in their experiment.
threshold	Genomic regions with this alignment read depth (or below) in the aligned synthetic read BAM are defined as low mappability regions.
n_threads	The number of threads used to calculate mappability exclusion regions from aligned bam file of synthetic reads.

Details

Creating a Mappability Exclusion BED file is a three-step process.

- First, using generateSyntheticReads(), synthetic reads are systematically generated using the given genome contained within reference_path, prepared via getResources. Alternatively, use alt_fasta_file to set the genome sequence if this is different to that prepared by getResources or if getResources is not yet run.
- Second, an aligner such as STAR (preferably the same aligner used for the subsequent RNA-seq experiment) is required to align these reads to the source genome. Poorly mapped regions of the genome will be reflected by regions of low coverage depth.
- Finally, the BAM file containing the aligned reads is analysed using calculateMappability(), to identify low-mappability regions to compile the Mappability Exclusion BED file.

It is recommended to leave all parameters to their default settings. Regular users should only specify reference_path, aligned_bam and n_threads, as required.

NB: STAR_mappability runs all 3 steps required, using the STAR aligner. This only works in systems where STAR is installed.

NB2: buildFullRef builds the STAR reference, then calculates mappability. It then uses the calculated mappability regions to build the SpliceWiz reference.

NB3: In systems where STAR is not available, consider using HISAT2 or Rsubread. A working example using Rsubread is shown below.

Value

- For generateSyntheticReads: writes Reads.fa to the Mappability subdirectory inside the given reference_path.
- For calculateMappability: writes a gzipped BED file named MappabilityExclusion.bed.gz to the Mappability subdirectory inside reference_path. This BED file is automatically used by buildRef if its MappabilityRef parameter is not specified.

Functions

- `generateSyntheticReads()`: Generates synthetic reads from a genome FASTA file, for mappability calculations.
- `calculateMappability()`: Generate a BED file defining low mappability regions, using reads generated by `generateSyntheticReads()`, aligned to the genome.

See Also

Build-Reference-methods

Examples

```
# (1a) Creates genome resource files

ref_path <- file.path(tempdir(), "refWithMapExcl")

getResources(
    reference_path = ref_path,
    fasta = chrZ_genome(),
    gtf = chrZ_gtf()
)

# (1b) Systematically generate reads based on the example genome:

generateSyntheticReads(
    reference_path = ref_path
)
## Not run:

# (2) Align the generated reads using Rsubread:

# (2a) Build the Rsubread genome index:

setwd(ref_path)
Rsubread::buildindex(basename = "./reference_index",
    reference = chrZ_genome())

# (2b) Align the synthetic reads using Rsubread::subjunc()

Rsubread::subjunc(
    index = "./reference_index",
    readfile1 = file.path(ref_path, "Mappability", "Reads.fa"),
    output_file = file.path(ref_path, "Mappability", "AlignedReads.bam"),
    useAnnotation = TRUE,
    annot.ext = chrZ_gtf(),
    isGTF = TRUE
)

# (3) Analyse the aligned reads in the BAM file for low-mappability regions:

calculateMappability(
```

```
    reference_path = ref_path,
    aligned_bam = file.path(ref_path, "Mappability", "AlignedReads.bam")
)

# (4) Build the example reference using the calculated Mappability Exclusions

buildRef(ref_path)

# NB the default is to search for the BED file generated by
# `calculateMappability()` in the given reference_path

## End(Not run)
```

NxtSE-class *The NxtSE class*

Description

The NxtSE class inherits from the SummarizedExperiment class and is constructed using makeSE. NxtSE extends SummarizedExperiment by housing additional assays pertaining to IR and splice junction counts.

Usage

```
NxtSE(...)

## S4 method for signature 'NxtSE'
up_inc(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
down_inc(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
up_exc(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
down_exc(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
covfile(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
sampleQC(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
ref(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
```

```
junc_PSI(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
junc_counts(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
junc_gr(x, withDimnames = TRUE, ...)

## S4 method for signature 'NxtSE'
realize_NxtSE(x, includeJunctions = FALSE, withDimnames = TRUE, ...)

## S4 replacement method for signature 'NxtSE'
up_inc(x, withDimnames = TRUE) <- value

## S4 replacement method for signature 'NxtSE'
down_inc(x, withDimnames = TRUE) <- value

## S4 replacement method for signature 'NxtSE'
up_exc(x, withDimnames = TRUE) <- value

## S4 replacement method for signature 'NxtSE'
down_exc(x, withDimnames = TRUE) <- value

## S4 replacement method for signature 'NxtSE'
covfile(x, withDimnames = TRUE) <- value

## S4 replacement method for signature 'NxtSE'
sampleQC(x, withDimnames = TRUE) <- value

## S4 method for signature 'NxtSE,ANY,ANY,ANY'
x[i, j, ..., drop = TRUE]

## S4 replacement method for signature 'NxtSE,ANY,ANY,NxtSE'
x[i, j, ...] <- value

## S4 method for signature 'NxtSE'
cbind(..., deparse.level = 1)

## S4 method for signature 'NxtSE'
rbind(..., deparse.level = 1)
```

Arguments

...	In NxtSE(), additional arguments to be passed onto SummarizedExperiment()
x	A NxtSE object
withDimnames	(default TRUE) Whether exported assays should be supplied with row and column names of the NxtSE object. See SummarizedExperiment

includeJunctions
: When realizing a NxtSE object, include whether junction counts and PSIs should be realized into memory. Not recommended for general use, as they are only used for coverage plots.

value
: The value to replace. Must be a matrix for the up_inc<-, down_inc<-, up_exc<- and down_exc<- replacers, and a character vector for covfile<-

i, j
: Row and column subscripts to subset a NxtSE object.

drop
: A logical(1), ignored by these methods.

deparse.level
: See base::cbind for a description of this argument.

Value

See Functions section (below) for details

Functions

- `NxtSE()`: Constructor function for NxtSE; akin to SummarizedExperiment(...)
- `up_inc(NxtSE)`: Gets upstream included events (SE/MXE), or upstream exon-intron spanning reads (IR)
- `down_inc(NxtSE)`: Gets downstream included events (SE/MXE), or downstream exon-intron spanning reads (IR)
- `up_exc(NxtSE)`: Gets upstream excluded events (MXE only)
- `down_exc(NxtSE)`: Gets downstream excluded events (MXE only)
- `covfile(NxtSE)`: Gets a named vector with the paths to the corresponding COV files
- `sampleQC(NxtSE)`: Gets a data frame with the QC parameters of the samples
- `ref(NxtSE)`: Retrieves a list of annotation data associated with this NxtSE object; primarily used in plotCoverage()
- `junc_PSI(NxtSE)`: Getter for junction PSI DelayedMatrix; primarily used in plotCoverage()
- `junc_counts(NxtSE)`: Getter for junction counts DelayedMatrix; primarily used in plotCoverage()
- `junc_gr(NxtSE)`: Getter for junction GenomicRanges coordinates; primarily used in plotCoverage()
- `realize_NxtSE(NxtSE)`: Converts all DelayedMatrix assays as matrices (i.e. performs all delayed calculation and loads resulting object to RAM)
- `up_inc(NxtSE) <- value`: Sets upstream included events (SE/MXE), or upstream exon-intron spanning reads (IR)
- `down_inc(NxtSE) <- value`: Sets downstream included events (SE/MXE), or downstream exon-intron spanning reads (IR)
- `up_exc(NxtSE) <- value`: Sets upstream excluded events (MXE only)
- `down_exc(NxtSE) <- value`: Sets downstream excluded events (MXE only)
- `covfile(NxtSE) <- value`: Sets the paths to the corresponding COV files
- `sampleQC(NxtSE) <- value`: Sets the values in the data frame containing sample QC

- `x[i`: Subsets a NxtSE object
- `` `[`(x = NxtSE, i = ANY, j = ANY) <- value ``: Sets a subsetted NxtSE object
- `cbind(NxtSE)`: Combines two NxtSE objects (by samples - columns)
- `rbind(NxtSE)`: Combines two NxtSE objects (by AS/IR events - rows)

Examples

```
# Run the full pipeline to generate a NxtSE object:

buildRef(
    reference_path = file.path(tempdir(), "Reference"),
    fasta = chrZ_genome(),
    gtf = chrZ_gtf()
)

bams <- SpliceWiz_example_bams()
processBAM(bams$path, bams$sample,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "SpliceWiz_Output")
)

expr <- findSpliceWizOutput(file.path(tempdir(), "SpliceWiz_Output"))
collateData(expr,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "Collated_output")
)

se <- makeSE(collate_path = file.path(tempdir(), "Collated_output"))

# Coerce NxtSE -> SummarizedExperiment
se_raw <- as(se, "SummarizedExperiment")

# Coerce SummarizedExperiment -> NxtSE
se_NxtSE <- as(se_raw, "NxtSE")
identical(se, se_NxtSE) # Returns TRUE

# Get Junction reads of SE / MXE and spans-reads of IR events
up_inc(se)
down_inc(se)
up_exc(se)
down_exc(se)

# Get list of available coverage files
covfile(se)

# Get sample QC information
sampleQC(se)

# Get resource data (used internally for plotCoverage())
cov_data <- ref(se)
names(cov_data)
```

```
# Subset functions
se_by_samples <- se[,1:3]
se_by_events <- se[1:10,]
se_by_rowData <- subset(se, EventType == "IR")

# Cbind (bind event_identical NxtSE by samples)
se_by_samples_1 <- se[,1:3]
se_by_samples_2 <- se[,4:6]
se_cbind <- cbind(se_by_samples_1, se_by_samples_2)
identical(se, se_cbind) # should return TRUE

# Rbind (bind sample_identical NxtSE by events)
se_IR <- subset(se, EventType == "IR")
se_SE <- subset(se, EventType == "SE")
se_IRSE <- rbind(se_IR, se_SE)
identical(se_IRSE, subset(se, EventType %in% c("IR", "SE"))) # TRUE

# Convert HDF5-based NxtSE to in-memory se
# makeSE() creates a HDF5-based NxtSE object where all assay data is stored
# as an h5 file instead of in-memory. All operations are performed as
# delayed operations as per DelayedArray package.
# To realize the NxtSE object as an in-memory object, use:

se_real <- realize_NxtSE(se)
identical(se, se_real) # should return FALSE

# To check the difference, run:
class(up_inc(se))
class(up_inc(se_real))
```

`plotCoverage` *RNA-seq Coverage Plots and Genome Tracks*

Description

Generate plotly / ggplot RNA-seq genome and coverage plots from command line. For some quick working examples, see the Examples section below.

Usage

```
plotCoverage(
  se,
  Event,
  Gene,
  seqname,
  start,
  end,
  coordinates,
```

```
  strand = c("*", "+", "-"),
  zoom_factor,
  bases_flanking = 100,
  tracks,
  track_names = tracks,
  condition,
  ribbon_mode = c("sd", "ci", "sem", "none"),
  selected_transcripts,
  plotJunctions = FALSE,
  plot_key_isoforms = FALSE,
  condense_tracks = FALSE,
  stack_tracks = FALSE,
  t_test = FALSE,
  norm_event
)

plotGenome(
  se,
  reference_path,
  Gene,
  seqname,
  start,
  end,
  coordinates,
  zoom_factor,
  bases_flanking = 100,
  selected_transcripts,
  condense_tracks = FALSE
)

as_ggplot_cov(p_obj)
```

Arguments

se	A NxtSE object, created by makeSE. COV files must be linked to the NxtSE object. To do this, see the example in makeSE. Required by `plotCoverage`. Not required by `plotGenome` if `reference_path` is supplied.
Event	The `EventName` of the IR / alternative splicing event to be displayed. Use `rownames(se)` to display a list of valid events.
Gene	Whether to use the range for the given `Gene`. If given, overrides `Event` (but `Event` or `norm_event` will be used to normalise by condition). Valid `Gene` entries include gene_id (Ensembl ID) or gene_name (Gene Symbol).
seqname, start, end	The chromosome (string) and genomic `start`/`end` coordinates (numeric) of the region to display. If present, overrides both `Event` and `Gene`. E.g. for a given region of chr1:10000-11000, use the parameters: `seqname = "chr1", start = 10000, end = 11000`
coordinates	A string specifying genomic coordinates can be given instead of `seqname,start,end`. Must be of the format "chr:start-end", e.g. "chr1:10000-11000"

`strand` Whether to show coverage of both strands "*" (default), or from the "+" or "-" strand only.

`zoom_factor` Zoom out from event. Each level of zoom zooms out by a factor of 3. E.g. for a query region of chr1:10000-11000, if a `zoom_factor` of 1.0 is given, chr1:99000-12000 will be displayed.

`bases_flanking` (Default = `100`) How many bases flanking the zoomed window. Useful when used in conjunction with zoom_factor == 0. E.g. for a given region of chr1:10000-11000, if `zoom_factor = 0` and `bases_flanking = 100`, the region chr1:9900-11100 will be displayed.

`tracks` The names of individual samples, or the names of the different conditions to be plotted. For the latter, set `condition` to the specified condition category.

`track_names` The names of the tracks to be displayed. If omitted, the track_names will default to the input in `tracks`

`condition` To display normalised coverage per condition, set this to the condition category. If omitted, `tracks` are assumed to refer to the names of individual samples.

`ribbon_mode` (default `"sd"`) Whether coverage ribbons signify standard deviation `"sd"`, 95% confidence interval `"ci"`, standard error of the mean `"sem"`, or none `"none"`. Only applicable when `condition` is set.

`selected_transcripts`
(Optional) A vector containing transcript ID or transcript names of transcripts to be displayed on the gene annotation track. Useful to remove minor isoforms that are not relevant to the samples being displayed.

`plotJunctions` (default `FALSE`) If `TRUE`, sashimi plot junction arcs are plotted. Currently only implemented for plots of individual samples.

`plot_key_isoforms`
(default `FALSE`) If `TRUE`, only transcripts involved in the selected `Event` or pair of `Events` will be displayed.

`condense_tracks`
(default `FALSE`) Whether to collapse the transcript track annotations by gene.

`stack_tracks` (default `FALSE`) Whether to graph all the conditions on a single coverage track. If set to `TRUE`, each condition will be displayed in a different colour on the same track. Ignored if `condition` is not set.

`t_test` (default `FALSE`) Whether to perform a pair-wise T-test. Only used if there are TWO condition tracks.

`norm_event` Whether to normalise by an event different to that given in "Event". The difference between this and Event is that the genomic coordinates can be centered around a different `Event`, `Gene` or region as given in `seqname/start/end`. If `norm_event` is different to `Event`, `norm_event` will be used for normalisation and `Event` will be used to define the genomic coordinates of the viewing window. `norm_event` is required if `Event` is not set and `condition` is set.

`reference_path` The path of the reference generated by Build-Reference-methods. Required by `plotGenome` if a NxtSE object is not specified.

`p_obj` In `as_ggplot_cov`, takes the output of `plotCoverage` and plots all tracks in a static plot using `ggarrange` function of the `egg` package. Requires `egg` package to be installed.

Details

In RNA sequencing, alignments to spliced transcripts will "skip" over genomic regions of introns. This can be illustrated in a plot using a horizontal genomic axis, with the vertical axis representing the number of alignments covering each nucleotide. As a result, the coverage "hills" represent the expression of exons, and "valleys" to introns.

Different alternatively-spliced isoforms thus produce different coverage patterns. The change in the coverage across an alternate exon relative to its constitutively-included flanking exons, for example, represents its alternative inclusion or skipping. Similarly, elevation of intron valleys represent increased intron retention.

With multiple replicates per sample, coverage is dependent on library size and gene expression. To compare alternative splicing ratios, normalisation of the coverage of the alternate exon (or alternatively retained intron) relative to their constitutive flanking exons, is required. There is no established method for this normalisation, and can be confounded in situations where flanking elements are themselves alternatively spliced.

SpliceWiz performs this coverage normalisation using the same method as its estimate of spliced / intronic transcript abundance using the `SpliceOver` method (see details section in collateData). This normalisation can be applied to correct for library size and gene expression differences between samples of the same experimental condition. After normalisation, mean and variance of coverage can be computed as ratios relative to total transcript abundance. This method can visualise alternatively included genomic regions including casette exons, alternate splice site usage, and intron retention.

`plotCoverage` generates plots showing depth of alignments to the genomic axis. Plots can be generated for individual samples or samples grouped by experimental conditions. In the latter, mean and 95% confidence intervals are shown.

`plotGenome` generates genome transcript tracks only. Protein-coding regions are denoted by thick rectangles, whereas non-protein coding transcripts or untranslated regions are denoted with thin rectangles. Introns are denoted as lines.

Value

A list containing two objects (`final_plot` and `ggplot`). `final_plot` is the plotly object. `ggplot` is a list of ggplot tracks, with:

- `ggplot[[n]]` is the nth track (where n = 1, 2, 3 or 4).
- `ggplot[[5]]` contains the T-test track if one is generated.
- `ggplot[[6]]` always contains the genome track. A static plot can be generated using the `as_ggplot_cov` function.

Functions

- `plotCoverage()`: generates plots showing depth of alignments to the genomic axis. Plots can be generated for individual samples or samples grouped by experimental conditions. In the latter, mean and 95% confidence intervals are shown.
- `plotGenome()`: Generates a plot of transcripts within a given genomic region, or belonging to a specified gene
- `as_ggplot_cov()`: Coerce the `plotCoverage()` output as a vertically stacked ggplot, using egg::ggarrange

Examples

```
se <- SpliceWiz_example_NxtSE()

# Assign annotation of the experimental conditions
colData(se)$treatment <- rep(c("A", "B"), each = 3)

# Verify that the COV files are linked to the NxtSE object:
covfile(se)

# Plot the genome track only, with specified gene:
p <- plotGenome(se, Gene = "SRSF3")
p$ggplot

# View the genome track, specifying a genomic region via coordinates:
p <- plotGenome(se, coordinates = "chrZ:10000-20000")
p$ggplot

# Return a list of ggplot and plotly objects, also plotting junction counts
p <- plotCoverage(
    se = se,
    Event = "SE:SRSF3-203-exon4;SRSF3-202-int3",
    tracks = colnames(se)[1:4], plotJunctions = TRUE
)

# Display as a a static ggplot (requires the `egg` package to be installed):
as_ggplot_cov(p)

# Display the plotly-based interactive Coverage plot:
p$final_plot

# Plot by condition "treatment", including provisional PSIs
p <- plotCoverage(
    se = se,
    Event = "SE:SRSF3-203-exon4;SRSF3-202-int3",
    tracks = c("A", "B"), condition = "treatment", plotJunctions = TRUE
)
as_ggplot_cov(p)

# Select only transcripts involved in the selected alternative splicing event
p <- plotCoverage(
    se = se,
    Event = "SE:SRSF3-203-exon4;SRSF3-202-int3",
    tracks = colnames(se)[1:4],
    plot_key_isoforms = TRUE
)
as_ggplot_cov(p)
```

---

processBAM *Runs the OpenMP/C++ based SpliceWiz algorithm*

Description

These function calls the SpliceWiz C++ routine on one or more BAM files.

The routine is an improved version over the original IRFinder, with OpenMP-based multi-threading and the production of compact "COV" files to record alignment coverage. A SpliceWiz reference built using Build-Reference-methods is required.

After `processBAM()` is run, users should call collateData to collate individual outputs into an experiment / dataset.

BAM2COV creates COV files from BAM files without running `processBAM()`.

See details for performance info.

Usage

```
BAM2COV(
  bamfiles = "./Unsorted.bam",
  sample_names = "sample1",
  output_path = "./cov_folder",
  n_threads = 1,
  useOpenMP = TRUE,
  overwrite = FALSE,
  verbose = FALSE,
  multiRead = FALSE
)

processBAM(
  bamfiles = "./Unsorted.bam",
  sample_names = "sample1",
  reference_path = "./Reference",
  output_path = "./SpliceWiz_Output",
  n_threads = 1,
  useOpenMP = TRUE,
  overwrite = FALSE,
  run_featureCounts = FALSE,
  verbose = FALSE,
  multiRead = FALSE
)
```

Arguments

`bamfiles`	A vector containing file paths of 1 or more BAM files
`sample_names`	The sample names of the given BAM files. Must be a vector of the same length as `bamfiles`
`output_path`	The output directory of this function
`n_threads`	(default 1) The number of threads to use. See details.

useOpenMP (default TRUE) Whether to use OpenMP. If set to FALSE, BiocParallel will be used if n_threads is set

overwrite (default FALSE) If output files already exist, will not attempt to re-run. If run_featureCounts is TRUE, will not overwrite gene counts of previous run unless overwrite is TRUE.

verbose (default FALSE) Set to TRUE to allow processBAM() to output progress bars and messages

multiRead (default FALSE) Whether to use multiple threads to read files. Set to TRUE to use multiple threads (improves performance if files are already cached into memory.

reference_path The directory containing the SpliceWiz reference

run_featureCounts (default FALSE) Whether this function will run Rsubread::featureCounts on the BAM files after counting spliced reads. If so, the output will be saved to "main.FC.Rds in the output_path directory as a list object.

Details

Typical run-times for a 100-million paired-end alignment BAM file takes 10 minutes using a single core. Using 8 threads, the runtime is approximately 2-5 minutes, depending on your system's file input / output speeds. Approximately 10 Gb of RAM is used when OpenMP is used. If OpenMP is not used (see below), this memory usage is multiplied across the number of processor threads (i.e. 40 Gb if n_threads = 4).

OpenMP is natively available to Linux / Windows compilers, and OpenMP will be used if useOpenMP is set to TRUE, using multiple threads to process each BAM file. On Macs, if OpenMP is not available at compilation, BiocParallel will be used, processing BAM files simultaneously, with one BAM file per thread.

Value

processBAM() output will be saved to output_path. Output files will be named using the given sample names.

- sample.txt.gz: The main output file containing the quantitation of IR and splice junctions, as well as QC information
- sample.cov: Contains coverage information in compressed binary. See getCoverage
- main.FC.Rds: A single file containing gene counts for the whole dataset (only if run_featureCounts == TRUE)

Functions

- BAM2COV(): Converts BAM files to COV files without running processBAM()
- processBAM(): Processes BAM files. Requires a SpliceWiz reference generated by buildRef()

See Also

Build-Reference-methods collateData isCOV

Examples

```
# Run BAM2COV, which only produces COV files but does not run `processBAM()`:

bams <- SpliceWiz_example_bams()

BAM2COV(bams$path, bams$sample,
  output_path = file.path(tempdir(), "SpliceWiz_Output"),
  n_threads = 2, overwrite = TRUE
)

# Run processBAM(), which produces:
# - text output of intron coverage and spliced read counts
# - COV files which record read coverages

example_ref <- file.path(tempdir(), "Reference")

buildRef(
    reference_path = example_ref,
    fasta = chrZ_genome(),
    gtf = chrZ_gtf()
)

bams <- SpliceWiz_example_bams()

processBAM(bams$path, bams$sample,
  reference_path = file.path(tempdir(), "Reference"),
  output_path = file.path(tempdir(), "SpliceWiz_Output"),
  n_threads = 2
)
```

Run_SpliceWiz_Filters *Filtering for IR and Alternative Splicing Events*

Description

These function implements filtering of alternative splicing events, based on customisable criteria. See ASEFilter for details on how to construct SpliceWiz filters

Usage

```
getDefaultFilters()

applyFilters(se, filters = getDefaultFilters())

runFilter(se, filterObj)
```

Arguments

`se`	the NxtSE object to filter
`filters`	A vector or list of one or more ASEFilter objects. If left blank, the SpliceWiz default filters will be used.
`filterObj`	A single ASEFilter object.

Details

We highly recommend using the default filters, which are as follows:

- (1) Depth filter of 20,
- (2) Participation filter requiring 70% coverage in IR events.
- (3) Participation filter requiring 40% coverage in SE, A5SS and A3SS events (i.e. Included + Excluded isoforms must cover at least 40% of all junction events across the given region)
- (4) Consistency filter requring log difference of 2 (for skipped exon and mutually exclusive exon events, each junction must comprise at least 1/(2^2) = 1/4 of all reads associated with each isoform). For retained introns, the exon-intron overhangs must not differ by 1/4
- (5) Terminus filter: In alternate first exons, the splice junction must not be shared with another transcript for which it is not its first intron. For alternative last exons, the splice junction must not be shared with another transcript for which it is not its last intron
- (6) ExclusiveMXE filter: For MXE events, the two alternate casette exons must not overlap in their genomic regions

In all data-based filters, we require at least 80% samples (`pcTRUE = 80`) to pass this filters from the entire dataset (`minCond = -1`).

Events with event read depth (reads supporting either included or excluded isoforms) lower than 5 (`minDepth = 5`) are not assessed in filter #2, and in #3 and #4 this threshold is (`minDepth = 20`).

For an explanation of the various parameters mentioned here, see ASEFilter

Value

For `runFilter` and `applyFilters`: a vector of type `logical`, representing the rows of NxtSE that should be kept.

For `getDefaultFilters`: returns a list of default recommended filters that should be parsed into `applyFilters`.

Functions

- `getDefaultFilters()`: Returns a vector of recommended default SpliceWiz filters
- `applyFilters()`: Run a vector or list of ASEFilter objects on a NxtSE object
- `runFilter()`: Run a single filter on a NxtSE object

See Also

ASEFilter for details describing how to create and assign settings to ASEFilter objects.

Examples

```
# see ?makeSE on example code of how this object was generated

se <- SpliceWiz_example_NxtSE()

# Get the list of SpliceWiz recommended filters

filters <- getDefaultFilters()

# View a description of what these filters do:

filters

# Filter the NxtSE using the first default filter ("Depth")

se.depthfilter <- se[runFilter(se, filters[[1]]), ]

# Filter the NxtSE using all four default filters

se.defaultFiltered <- se[applyFilters(se, getDefaultFilters()), ]
```

---

setSWthreads *Sets the number of threads used by SpliceWiz*

Description

SpliceWiz uses the computationally efficient packages `fst` and `data.table` to compute file and data operations, respectively. Both packages make use of parallelisation. If excessive number of threads are allocated, it may impact the running of other operations on your system. Use this function to manually allocate the desired number of threads

Usage

```
setSWthreads(threads = 0)
```

Arguments

`threads`	(default `0`) The number of threads for SpliceWiz to use. Set as `0` to use the recommended number of threads appropriate for the system (approximately half the available threads)

Value

Nothing.

Examples

```
setSWthreads(0)
```

STAR-methods *STAR wrappers for building reference for STAR, and aligning RNA-sequencing*

Description

These functions run the STAR aligner to build a STAR genome reference, calculate mappability exclusion regions using STAR, and align one or more FASTQ files (single or paired) to the generated genome. These functions only work on Linux-based systems with STAR installed. STAR must be accessible via `$PATH`. See details and examples

Usage

```
STAR_version()

STAR_buildRef(
  reference_path,
  STAR_ref_path = file.path(reference_path, "STAR"),
  also_generate_mappability = TRUE,
  map_depth_threshold = 4,
  sjdbOverhang = 149,
  n_threads = 4,
  additional_args = NULL,
  ...
)

STAR_mappability(
  reference_path,
  STAR_ref_path = file.path(reference_path, "STAR"),
  map_depth_threshold = 4,
  n_threads = 4,
  ...
)

STAR_alignExperiment(
  Experiment,
  STAR_ref_path,
  BAM_output_path,
  trim_adaptor = "AGATCGGAAG",
  two_pass = FALSE,
  n_threads = 4
)

STAR_alignReads(
  fastq_1 = c("./sample_1.fastq"),
  fastq_2 = NULL,
  STAR_ref_path,
```

```
  BAM_output_path,
  two_pass = FALSE,
  trim_adaptor = "AGATCGGAAG",
  memory_mode = "NoSharedMemory",
  additional_args = NULL,
  n_threads = 4
)
```

Arguments

reference_path	The path to the reference. getResources must first be run using this path as its reference_path
STAR_ref_path	(Default - the "STAR" subdirectory under reference_path) The directory containing the STAR reference to be used or to contain the newly-generated STAR reference
also_generate_mappability	Whether STAR_buildRef() also calculates Mappability Exclusion regions.
map_depth_threshold	(Default 4) The depth of mapped reads threshold at or below which Mappability exclusion regions are defined. See Mappability-methods. Ignored if also_generate_mappability = FALSE
sjdbOverhang	(Default = 149) A STAR setting indicating the length of the donor / acceptor sequence on each side of the junctions. Ideally equal to (mate_length - 1). As the most common read length is 150, the default of this function is 149. See the STAR aligner manual for details.
n_threads	The number of threads to run the STAR aligner.
additional_args	A character vector of additional arguments to be parsed into STAR. See examples below.
...	Additional arguments to be parsed into generateSyntheticReads(). See Mappability-methods.
Experiment	A two or three-column data frame with the columns denoting sample names, forward-FASTQ and reverse-FASTQ files. This can be conveniently generated using findFASTQ
BAM_output_path	The path under which STAR outputs the aligned BAM files. In STAR_alignExperiment(), STAR will output aligned BAMS inside subdirectories of this folder, named by sample names. In STAR_alignReads(), STAR will output directly into this path.
trim_adaptor	The sequence of the Illumina adaptor to trim via STAR's --clip3pAdapterSeq option
two_pass	Whether to use two-pass mapping. In STAR_alignExperiment(), STAR will first align every sample and generate a list of splice junctions but not BAM files. The junctions are then given to STAR to generate a temporary genome (contained within _STARgenome) subdirectory within that of the first sample), using these junctions to improve novel junction detection. In STAR_alignReads(), STAR will run --twopassMode Basic

`fastq_1, fastq_2`
: In STAR_alignReads: character vectors giving the path(s) of one or more FASTQ (or FASTA) files to be aligned. If single reads are to be aligned, omit `fastq_2`

`memory_mode`
: The parameter to be parsed to `--genomeLoad`; either `NoSharedMemory` or `LoadAndKeep` are used.

Details

Pre-requisites

`STAR_buildRef` requires getResources to be run to fetch the required genome and gene annotation files.

`STAR_mappability`, `STAR_alignExperiment` and `STAR_alignReads` requires a `STAR` genome, which can be built using `STAR_buildRef`

Function Description

For `STAR_buildRef`: this function will create a `STAR` genome reference in the `STAR` subdirectory in the path given by `reference_path`. Optionally, it will run `STAR_mappability` if `also_generate_mappability` is set to `TRUE`

For `STAR_mappability`: this function will first will run generateSyntheticReads, then use the given `STAR` genome to align the synthetic reads using `STAR`. The aligned BAM file will then be processed using calculateMappability to calculate the lowly-mappable genomic regions, producing the `MappabilityExclusion.bed.gz` output file.

For `STAR_alignReads`: aligns a single or pair of FASTQ files to the given `STAR` genome using the `STAR` aligner.

For `STAR_alignExperiment`: aligns a set of FASTQ or paired FASTQ files using the given `STAR` genome using the `STAR` aligner. A data.frame specifying sample names and corresponding FASTQ files are required

Value

None. STAR will output files into the given output directories.

Functions

- `STAR_version()`: Checks whether STAR is installed, and its version
- `STAR_buildRef()`: Creates a STAR genome reference.
- `STAR_mappability()`: Calculates lowly-mappable genomic regions using STAR
- `STAR_alignExperiment()`: Aligns multiple sets of FASTQ files, belonging to multiple samples
- `STAR_alignReads()`: Aligns a single sample (with single or paired FASTQ or FASTA files)

    two_pass = TRUE,
    n_threads = 8
)

## End(Not run)
```

`theme_white` *ggplot2 themes*

Description

A ggplot theme object for white background figures +/- a legend

Usage

```
theme_white

theme_white_legend

theme_white_legend_plot_track
```

Format

An object of class theme (inherits from gg) of length 10.

An object of class theme (inherits from gg) of length 9.

An object of class theme (inherits from gg) of length 10.

Functions

- theme_white: White theme without figure legend
- theme_white_legend: White theme but with a figure legend (if applicable)
- theme_white_legend_plot_track: White theme with figure legend but without horizontal grid lines. Used internally in PlotGenome

  geom_point() +
  theme_white
```

View-Reference-methods

View SpliceWiz Reference in read-able data frames

Description

These functions allow users to construct tables containing SpliceWiz's reference of alternate splicing events, intron retention events, and other relevant data

Usage

```
viewASE(reference_path)

viewIR(reference_path, directional = TRUE)

viewIntrons(reference_path)

viewIR_NMD(reference_path)

viewExons(reference_path)
```

```
viewGenes(reference_path)

viewProteins(reference_path)

viewTranscripts(reference_path)
```

Arguments

reference_path	The directory containing the SpliceWiz reference
directional	(default TRUE) Whether to view IR events for stranded RNAseq TRUE or unstranded protocol FALSE

Value

A data frame containing the relevant info. See details

Functions

- viewASE(): Outputs summary of alternative splicing events constructed by SpliceWiz
- viewIR(): Outputs summary of assessed IRFinde-like IR events, constructed by SpliceWiz
- viewIntrons(): Outputs summary of all introns from the annotation, constructed by SpliceWiz
- viewIR_NMD(): Outputs information for every intron - whether retention of the intron will convert the transcript to an NMD substrate
- viewExons(): Outputs information for every exon from the annotation.
- viewGenes(): Outputs information for every gene from the annotation.
- viewProteins(): Outputs information for every protein-coding exon from the annotation.
- viewTranscripts(): Outputs information for every transcript from the annotation.
