Package 'vsclust'

January 23, 2025

Encoding UTF-8

Type Package

Title Feature-based variance-sensitive quantitative clustering

Version 1.9.10

Date 2022-03-23

Description Feature-based variance-sensitive clustering of omics data. Optimizes cluster assignment by taking into account individual feature variance. Includes several modules for statistical testing, clustering and enrichment analysis.

License GPL-2

Imports matrixStats, limma, parallel, shiny, qvalue, grDevices, stats, MultiAssayExperiment, graphics

Suggests knitr, yaml, testthat (>= 3.0.0), rmarkdown, BiocStyle, clusterProfiler, httr

LinkingTo Rcpp

biocViews Clustering, Annotation, PrincipalComponent, DifferentialExpression, Visualization, Proteomics, Metabolomics

VignetteBuilder knitr

Depends R (>= 4.2.0)

Config/testthat/edition 3

Contents

`vsclust-package` *VSClust provides a powerful method to run variance-sensitive clustering*

Description

Clustering of high-dimensional quantitative data with data points that come with multiple measurements. In this clustering method, each feature is represented by a) its quantitative profile and b) its variance. Hence, the incertainty about a measurement enter in the determination of the most common patterns. This methods is both insensitive to noisy measurements and avoids finding clusters in homogeneously distributed data.

Details

The functions in this package comprise (i) methods to prepare the data for cluster analysis like statistical analysis (‘SignAnal‘and SignPairedAnal‘), PCA (‘PCAwithVar‘), (ii) direct application of the clustering algorithm on a (standardized) data matrix (‘vsclust_algorithm‘), (iii) for the further evaluation and visualization (such as ‘calcBHI‘ and ‘mfuzz.plot‘), and (iv) wrappers for the over workflow including statistical preparation (‘statWrapper‘), estimation of the cluster number (‘estimClustNum‘), running the clustering (‘runClustWrapper‘) and functional evaluation (‘runFuncEnrich‘).

---

artificial_clusters *Synthetic/artificial data comprising 5 clusters*

Description

10-dimensional data set with 500 simulating features measured over 5 replicates each, comprising a total of 50 samples. The first 250 features were modeled through normal distributions shifted in the 10-dimensional space to form 5 different clusters. The 2nd half of the features were modeled through a normal distribution around the origin and thus should be assigned to any cluster

Usage

```
artificial_clusters
```

Format

A data frame consisting of 500 features distributed over 5 clusters and being replicated 5 times each

Source

Protein Research Group, University of Southern Denmark, Odense

averageCond *Calculate mean over replicates*

Description

Simple method to calculate the means for each feature across its replicates

Usage

```
averageCond(data, NumReps, NumCond)
```

Arguments

data	Matrix of data frame with numerical values. Columns corresponds to samples
NumReps	Number of replicates per experimental condition
NumCond	Number of different experimental conditions

Value

Matrix of data frame with averaged values over replicates for each conditions

Examples

```
data <- matrix(rnorm(1000), nrow=100)
av_data <- averageCond(data, NumCond=2, NumReps=5)
```

calcBHI *Calculate "biological homogeneity index"*

Description

This index is providing a number for the enriched GO terms and pathways to assess the biological content within a set of genes or proteins. The calculation is according to Datta, S. & Datta, S. Methods for evaluating clustering algorithms for gene expression data using a reference set of functional classes. BMC bioinformatics 7, 397 (2006).

Usage

```
calcBHI(Accs, gos)
```

Arguments

Accs	list containing gene or protein IDs, such as UniProt accession names
gos	object from ClusterProfiler

Value

Biological Homogeneity Index

Schwaemmle V, Jensen ON. A simple and fast method to determine the parameters for fuzzy c-means cluster analysis. Bioinformatics. 2010 Nov 15;26(22):2841-8. doi: 10.1093/bioinformatics/btq534. Epub 2010 Sep 29. PMID: 20880957.

Examples

```
# Run enrichment analysis
data(gcSample, package="clusterProfiler")
xx <- clusterProfiler::compareCluster(gcSample, fun="enrichKEGG",
                    organism="hsa", pvalueCutoff=0.05)
# Generate random list from gcSample
rand_ids <- lapply(gcSample, function(x) sample(unlist(gcSample), 200))
calcBHI(rand_ids, xx)
```

ClustComp *Function to run clustering with automatic fuzzifier settings (might become obsolete)*

Description

Run original fuzzy c-means and vsclust for a number of clusters and the given data set including data pre-processing and automatic setting of the data-dependent parameters like the lower limit of the fuzzifier.

Usage

```
ClustComp(
  dat,
  NSs = 10,
  NClust = NClust,
  Sds = Sds,
  cl = parallel::makePSOCKcluster(1),
  verbose = FALSE
)
```

Arguments

dat	a numeric data matrix
NSs	number of clusterings runs with different random seeds
NClust	Number of clusters
Sds	Standard deviation of features (either vector of the same length as features numbers in matrix or single value)
cl	object of class ‘cluster‘ or ‘SOCKcluster‘ to specify environment for parallelization
verbose	Show more information during execution

Value

List containing the objects

‘indices‘ containing minimum centroid distance and Xie-Beni index for both clustering methods

‘Bestcl‘ optimal vsclust results (variance-sensitive fcm clustering)

‘Bestcl2‘ optimal fuzzy c-means restults

‘m‘ vector of individual fuzzifer values per feature

‘withinerror‘ final optimization score for vsclust

‘withinerror2‘ final optimization score for fuzzy c-means clustering

Examples

```
#' # Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Run clustering
cl <- parallel::makePSOCKcluster(1, nnodes=1)
ClustCompOut <- ClustComp(data, cl=cl, NClust=6, Sds=1)
barplot(ClustCompOut$indices)
```

cvalidate.xiebeni *Xie Beni Index of clustering object*

Description

Calculate the Xie Beni index for validity of the cluster number in clustering results from running fuzzy c-means or vsclust original publication:

Usage

```
cvalidate.xiebeni(clres, m)
```

Arguments

clres	Output from clustering. Either fclust object or list containing the objects for 'membership' and cluster 'centers'
m	Fuzzifier value

Value

Xie Beni index

References

Xie X.L., Beni G. (1991). A validity measure for fuzzy clustering, IEEE Transactions on Pattern Analysis and Machine Intelligence, 13, 841-847.

Examples

```
# Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Run clustering
clres <- vsclust_algorithm(data, centers=5, m=1.5)
# Calculate Xie-Beni index from results
cvalidate.xiebeni(clres, 1.5)
```

determine_fuzz *Determine individual fuzzifier values*

Description

This function calculated the values of the fuzzifier from a) the dimensions of the considered data set and b) from the individual feature standard deviations.

Usage

```
determine_fuzz(dims, NClust, Sds = 1)
```

Arguments

dims	vector of two integers containing the dimensions of the data matrix for the clustering
NClust	Number of cluster for running vsclust on (does no influence the calculation of 'mm')
Sds	individual standard deviations, set to 1 if not available

Value

list of 'm': individual fuzzifiers, 'mm': standard fuzzifier for fcm clustering when not using vsclust algorithm

Examples

```
# Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Estimate fuzzifiers
fuzz_out <- determine_fuzz(dim(data), 1)
# Run clustering
clres <- vsclust_algorithm(data, centers=5, m=fuzz_out$mm)
```

---

enrichSTRING_API *Enrichment Analysis via STRING REST API*

Description

enrichSTRING_API performs a functional enrichment analysis by sending a gene list to STRING's TSV API endpoint, retrieving enrichment results for one or more categories (e.g., "KEGG"), and building a clusterProfiler-style result object. It is intended as a lightweight replacement for older web-service–based methods like *RDAVIDWebService*.

Usage

```
enrichSTRING_API(
  genes,
  species = "none",
  category = "KEGG",
  adjpvalueCutoff = 0.05,
  verbose = FALSE
)
```

Arguments

genes	Character vector of gene or protein identifiers recognized by STRING.
species	A single numeric or string specifying the NCBI taxonomy ID (e.g., 9606 for human). If "none" (default), no species is set in the request, and STRING will attempt to auto-detect or may fail.
category	One or more enrichment categories from STRING (e.g., "KEGG", "Process", etc.). Defaults to "KEGG" if unspecified.
adjpvalueCutoff	Numeric cutoff for the BH-adjusted p-value (default 0.05).
verbose	Logical indicating whether to print diagnostic messages (default FALSE).

Details

This function:

1. Accepts a vector of genes recognized by STRING (e.g., Ensembl, UniProt, or commonly used gene symbols for a given species).
2. Sends a *POST* request to https://string-db.org/api/tsv/enrichment with those identifiers (and optionally species).
3. Parses the returned *TSV*-formatted enrichment data, which typically includes columns for term, description, p_value, and more.
4. Optionally filters by category (e.g., "KEGG", "Process", etc.), applies BH multiple-testing correction, and removes terms above the adjpvalueCutoff.
5. Returns an object of class enrichResult if *clusterProfiler* is installed; otherwise, it simply returns the filtered data frame.

Note that this function does *not* allow you to explicitly supply a custom background gene set. The STRING API by default uses the entire known set of genes or proteins for the specified species as the background. Also, the total number of background genes is not reported by STRING; only how many of them map to each term.

Value

If any terms pass the cutoff, an enrichResult object (from *clusterProfiler*) is returned. Otherwise, if *clusterProfiler* is not installed or no terms pass filtering, the function either returns a data.frame (if installed but no terms pass) or NULL.

See Also

STRING API documentation, clusterProfiler.

Examples

```
library(httr)

# A small gene set:
gene_set <- c("TP53","BRCA1","BRCA2","EGFR")

# Perform enrichment on KEGG terms for human (9606):
enr <- enrichSTRING_API(
          genes       = gene_set,
          species     = 9606,
          category    = "KEGG",
          adjpvalueCutoff = 0.05,
          verbose     = TRUE
       )

if (!is.null(enr)) {
  # If clusterProfiler is installed and some terms pass filtering, check results:
  head(enr@result)
}
```

---

estimClust.plot *Plotting results from estimating the cluster number*

Description

This function visualizes the output from estimClustNumber, and there particularly the two validity indices Minimum Centroid Distance and Xie Beni Index.

Usage

```
estimClust.plot(ClustInd)
```

Arguments

ClustInd	Matrix with values from validity indices

Value

Multiple panels showing expression profiles of clustered features passing the minMem threshold

References

Schwaemmle V, Jensen ON. VSClust: feature-based variance-sensitive clustering of omics data. Bioinformatics. 2018 Sep 1;34(17):2965-2972. doi: 10.1093/bioinformatics/bty224. PMID: 29635359.

Schwaemmle V, Hagensen CE. A Tutorial for Variance-Sensitive Clustering and the Quantitative Analysis of Protein Complexes. Methods Mol Biol. '2021;2228:433-451. doi: 10.1007/978-1-0716-1024-4_30. PMID: 33950508.

Schwaemmle V, Jensen ON. A simple and fast method to determine the parameters for fuzzy c-means cluster analysis. Bioinformatics. 2010 Nov 15;26(22):2841-8. doi: 10.1093/bioinformatics/btq534. Epub 2010 Sep 29. PMID: 20880957.

Examples

```
data("artificial_clusters")
dat <- averageCond(artificial_clusters, 5, 10)
dat <- scale(dat)
dat <- cbind(dat, 1)
ClustInd <- estimClustNum(dat, 6)
estimClust.plot(ClustInd)
```

`estimClustNum` *Wrapper for estimation of cluster number*

Description

This runs the clustering for different numbers of clusters, and estimates the most suitable numbers from applying the minimum centroid distance and the Xie Beni index. Multi-threading is used to shorten the computation times. Given the hierarchical structure of many data sets, the resulting numbers are suggestions. Inspection of the here plotted indices help to determine alternative cluster numbers, given by a strong decay of the minimum centroid distance and/or a low value of the Xie Beni index.

Usage

```
estimClustNum(dat, maxClust = 25, scaling = "standardize", cores = 1)
```

Arguments

`dat`	matrix of features averaged over replicates. The last column contains their standard deviation
`maxClust`	Maximal number of cluster. The minimum is 3
`scaling`	Either 'standardize' (default), 'center' or 'none'. Standardized features get mean 0 and standard deviation 1. Centered samples get mean 0.
`cores`	The number of threads to be used for parallelisation

Value

list with the items ‘ClustInd‘: list of clustering objects for each number of clusters, ‘p‘ plot object with plots for validity indices, ‘numclust‘ optimal cluster number according to "minimum centroid distance"

Examples

```
data <- matrix(rnorm(1000), nrow=100)
estim_out <- estimClustNum(data, maxClust=10)
best_number <- max(estim_out[1])
```

`mfuzz.plot` *Plotting vsclust results*

Description

This function visualizes the clustered quantitative profiles in multiple figure panels. The parameters allow specifying the main items like axes labels and color maps. The code is adopted from the MFuzz package.

Usage

```
mfuzz.plot(
  dat,
  cl,
  mfrow = c(1, 1),
  colo,
  minMem = 0,
  timeLabels,
  filename = NA,
  xlab = "Time",
  ylab = "Expression changes"
)
```

Arguments

`dat`	a numeric data matrix containing the values used in the clustering
`cl`	clustering results from vsclust_algorithm or Bestcl object from clustComp function
`mfrow`	vector of two numbers for the number of rows and colums, figure panels are distributed in the plot
`colo`	color map to be used (can be missing)
`minMem`	filter for showing only features with a higher membership values than this value
`timeLabels`	alternative labels for different conditions
`filename`	for writing into pdf. Will write on screen when using NA
`xlab`	Label of x-axis
`ylab`	Label of y-axis

Value

Multiple panels showing expression profiles of clustered features passing the minMem threshold

Examples

```
#' # Generate some random data
data <- matrix(rnorm(seq_len(5000)), nrow=500)
# Run clustering
clres <- vsclust_algorithm(data, centers=2, m=1.5)
mfuzz.plot(data, clres,  mfrow=c(2,3), minMem=0.0)
```

---

optimalClustNum *Determine optimal cluster number from validity index*

Description

Calculated the optimal number from expected behavior of the indices. This would be a large decay for the Minimum Centroid Distance and a minimum for the Xie Beni index

Usage

```
optimalClustNum(ClustInd, index = "MinCentroidDist", method = "VSClust")
```

Arguments

ClustInd	Output from estimClustNum providing the calculated cluster validity indices
index	Either "MinCentroidDist" or "XieBeni"
method	Either "VSClust" or "FCM" for standard fuzzy c-means clustering

Value

optimal cluster number

References

Examples

```
  data("artificial_clusters")
  dat <- averageCond(artificial_clusters, 5, 10)
  dat <- scale(dat)
dat <- cbind(dat, 1)
ClustInd <- estimClustNum(dat, 6)
optimalClustNum
```

`pcaWithVar` *Visualize using principal component analysis (both loadings and scoring) including the variance from the replicates*

Description

The loading plot shows all features and their scaled variance. This provides an idea of the intrinsic noise in the data.

Usage

```
pcaWithVar(data, NumReps, NumCond, Sds = 1)
```

Arguments

`data`	Matrix of data frame with numerical values. Columns corresponds to samples
`NumReps`	Number of replicates per experimental condition
`NumCond`	Number of different experimental conditions
`Sds`	Standard deviation for each features. Usually using the one from LIMMA

Value

Loading and scoring plots that include feature variance

References

Examples

```
data <- matrix(rnorm(1000), nrow=100)
pcaWithVar(data, NumCond=2, NumReps=5, Sds=1)
```

PrepareForVSClust *Functions for running VSClust analysis*

Description

Wrapper for statistical analysis

Usage

```
PrepareForVSClust(dat, NumReps, NumCond, isPaired = FALSE, isStat)
```

Arguments

dat	matrix or data frame of numerical data. Columns are samples. Replicates are grouped (i.e. A1, B1, C1, A2, B2, C2) when letters denote conditions and numbers the replicates. In case of 'isStat=FALSE', you need a last column for the standard deviations
NumReps	Number replicates in the data
NumCond	Number of different experimental conditions. The total number of columns needs to be NumReps*NumCond
isPaired	Boolean for running paired or unpaired statistical tests
isStat	Boolean for whether to run statistical test or each column corresponds to a different experimental conditions. Then this function reads feature standard deviations from data frame from the last column

Details

Prepare data for running vsclust clustering. This includes visualization running the functions for the principal component analysis and its visualization, statistical testing with LIMMA, as well as scaling and filtering of missing values

Value

list with the items ‘dat‘ (data matrix of features averaged over replicates and last column with their standard deviations), ‘qvals‘ FDRs from the statistical tests (each conditions versus the first), ‘StatFileOut‘ all of before for saving in file

References

Schwaemmle V, Jensen ON. VSClust: feature-based variance-sensitive clustering of omics data. Bioinformatics. 2018 Sep 1;34(17):2965-2972. doi: 10.1093/bioinformatics/bty224. PMID: 29635359.

Schwaemmle V, Hagensen CE. A Tutorial for Variance-Sensitive Clustering and the Quantitative Analysis of Protein Complexes. Methods Mol Biol. 2021;2228:433-451. doi: 10.1007/978-1-0716-1024-4_30. PMID: 33950508.

Examples

```
data <- matrix(rnorm(2000), nrow=200)
stats <- PrepareForVSClust(data, 5, 2, isStat=TRUE)
```

`PrepareSEForVSClust` *Wrapper for statistical analysis for SummarizedExperiment object*

Description

Prepare data for running vsclust clustering. This includes visualization running the functions for the principal component analysis and its visualization, statistical testing with LIMMA, as well as scaling and filtering of missing values

Usage

```
PrepareSEForVSClust(
  se,
  assayname = 1,
  coldatname = NULL,
  isPaired = FALSE,
  isStat
)
```

Arguments

`se`	SummarizedExperiment object
`assayname`	Sample in SummarizedExperiment object
`coldatname`	Column in colData for extracting replicates

isPaired	Boolean for running paired or unpaired statistical tests
isStat	Boolean for whether to run statistical test or each column corresponds to a different experimental conditions. Then this function reads feature standard deviations from data frame from the last column

Value

list with the items 'dat' (data matrix of features averaged over replicates and last column with their standard deviations), 'qvals' FDRs from the statistical tests (each conditions versus the first), 'StatFileOut' all of before for saving in file, 'NumReps' number of replicates and 'NumCond' number of different experimental conditions

Examples

```
data(miniACC, package="MultiAssayExperiment")

stats <- PrepareSEForVSClust(miniACC, coldatname="COC", isStat=TRUE)
```

---

protein_expressions *Data from a typical proteomics experiment*

Description

There are 12 samples coming from mouse fed with the four different diets, measured in three replicates each. Relative protein abundances were obtained using iTRAQ labelling. The given numbers are log2-transformed. Protein names as UniProt accession numbers are given as rownames.

Usage

```
protein_expressions
```

Format

A data frame consisting of 574 proteins measured in 12 samples:

HF.Rep.1 Mice fed with a high fat diet, replicate 1

HF.Rep.2 Mice fed with a high fat diet, replicate 2

`runClustWrapper` *Wrapper for running cluster analysis*

Description

This function runs the clustering and visualizes the results.

Usage

```
runClustWrapper(
  dat,
  NClust,
  proteins = NULL,
  VSClust = TRUE,
  scaling = "standardize",
  cores,
  verbose = FALSE
)
```

Arguments

dat	matrix or data frame with feature values for different conditions
NClust	Number of cluster for running the clustering
proteins	vector with additional feature information (default is NULL) to be added to the results
VSClust	boolean. TRUE for running the variance-sensitive clustering. Otherwise, the function will call standard fuzzy c-means clustering
scaling	Either 'standardize' (default), 'center' or 'none'. Standardized features get mean 0 and standard deviation 1. Centered samples get mean 0.
cores	Number of threads for the parallelization
verbose	Show more information during execution

Value

list with the items 'dat'(the original data), 'Bestcl' clustering results (same as from vsclust_algorithm), 'p' (plot object with mfuzz plots), 'outFileClust'(suitable matrix with complete information) , 'ClustInd' (information about being member of any cluster, feature needs on membership values > 0.5)

Examples

```
data(iris)
data <- cbind(iris[,seq_len(4)],1)
clust_out <- runClustWrapper(data, NClust=3, cores=1)
clust_out$p
```

---

runFuncEnrich *Functional Enrichment with STRING*

Description

runFuncEnrich performs a functional enrichment analysis for each cluster of features (genes/proteins) using an enrichSTRING_API call (which queries the STRING database). It replaces a previously used approach that relied on *RDAVIDWebService*, and is therefore more up to date.

Usage

```
runFuncEnrich(cl, protnames = NULL, infosource)
```

Arguments

cl	A clustering result. Typically either the direct output of vsclust_algorithm or a Bestcl object from ClustComp or runClustWrapper.
protnames	Optional named vector mapping feature IDs (as in cl$cluster) to more interpretable gene/protein identifiers. If NULL (the default), the feature names in cl themselves are used.
infosource	Currently unused; previously indicated enrichment categories when using DAVID. Kept for compatibility but is ignored in this version.

Details

The function takes a clustering result (e.g., from `vsclust_algorithm` or `Bestcl` objects) and, for each cluster:

1. Extracts the member features with membership above 0.5.
2. Optionally replaces their IDs with entries from `protnames`.
3. Calls `compareCluster` (from *clusterProfiler*) using a custom `enrichSTRING_API` function for the actual STRING-based enrichment.

The resulting `compareClusterResult` includes adjusted p-values (FDR), and the top 20 enriched terms are retained if the total set is larger than 20.

Value

A list with three components:

`fullFuncs` The full `compareCluster` result from `enrichSTRING_API`.

`redFuncs` A `compareClusterResult` object containing only the top 20 enriched terms (if more than 20 were detected).

`BHI` A numeric value from `calcBHI` measuring cluster heterogeneity.

See Also

`compareCluster`, `enrichSTRING_API`

Examples

```
## Not run:
  # Suppose 'mycl' is a clustering result from vsclust_algorithm,
  # and we have a named vector 'myProtnames' that maps feature IDs to gene symbols:

  res <- runFuncEnrich(mycl, protnames = myProtnames)
  res$fullFuncs  # The full compareCluster output
  res$redFuncs   # The top 20 enriched terms
  res$BHI        # The numeric BHI value

## End(Not run)
```

`runVSClustApp` *Run VSClust as Shiny app*

Description

You will get the full functionality of the VSClust workflow with multiple visualizations and downloads

Usage

```
runVSClustApp()
```

Value

The shiny app should open in a browser or in RStudio.

Examples

```
## Not run:
runVSClustApp()
## End(Not run)
```

SignAnalysis *Unpaired statistical testing*

Description

Statistical testing and variance estimation in multi-dimensional data set. given by a matrix. This functions runs LIMMA paired tests and calculated the shrunken variance estimates.

Usage

```
SignAnalysis(Data, NumCond, NumReps)
```

Arguments

Data	a numeric data matrix with columns as samples. Different experimental conditions are grouped together in their replicates. The number of samples per group needs to be identical
NumCond	Number of different experimental conditions
NumReps	Number of replicates per experimental condition

Value

List containing the objects

'pvalues' p-values before correction for multiple testing

'qvalues' false discovery rates after correction for multiple testing ('qvalue' method from 'qvalue' library)

'Sds' General standard deviation within replicates after using shrinkage by LIMMA

References

Examples

```
#' # Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Run statistical testing
stat_out <- SignAnalysis(data, 2, 5)
# Histogram of qvalues (no significant events)
hist(stat_out$qvalues, 50, xlab="q-values")
```

SignAnalysisPaired *Paired statistical testing*

Description

Statistical testing and variance estimation in multi-dimensional data set. given by a matrix. This functions runs LIMMA paired tests and calculated the shrunken variance estimates.

Usage

```
SignAnalysisPaired(Data, NumCond, NumReps)
```

Arguments

Data	a numeric data matrix with columns as samples. Different experimental conditions are grouped together in their replicates. The number of samples per group needs to be identical
NumCond	Number of different experimental conditions
NumReps	Number of replicates per experimental condition

Value

List containing the objects

'qvalues' false discovery rates after correction for multiple testing ('qvalue' method from 'qvalue' library)

'Sds' General standard deviation within replicates after using shrinkage (eBayes) by LIMMA

Examples

```
#' # Generate some random data with three different experimental conditions
data <- matrix(rnorm(seq_len(1500)), nrow=100)
# Run statistical testing
stat_out <- SignAnalysisPaired(data, 3, 5)
# Histogram of qvalues comparing the second to the first condition
hist(stat_out$qvalues[,1], 50, xlab="q-values")
```

SwitchOrder *arrange cluster member numbers from largest to smallest*

Description

arrange cluster member numbers from largest to smallest

Usage

```
SwitchOrder(Bestcl, NClust)
```

Arguments

Bestcl	fclust object
NClust	Number of clusters

Value

fclust object with reorder clusters

Examples

```
# Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Run clustering
clres <- vsclust_algorithm(data, centers=5, m=1.5)
clres <- SwitchOrder(clres, 5)
```

`vsclust_algorithm` *Run the vsclust clustering algorithm*

Description

This function calls the c++ implementation of the vsclust algorithm, being an extension of fuzzy c-means clustering with additional variance control and capability to run on data with missing values

Usage

```
vsclust_algorithm(
  x,
  centers,
  iterMax = 100,
  verbose = FALSE,
  dist = "euclidean",
  m = 2,
  ratePar = NULL,
  weights = 1,
  control = list()
)
```

Arguments

`x`	a numeric data matrix
`centers`	Either numeric for number of clusters or numeric matrix with center coordinates
`iterMax`	Numeric for maximum number of iterations
`verbose`	Verbose information
`dist`	Distance to use for the calculation. We prefer "euclidean" (default)
`m`	Fuzzifier value: numeric or vector of length equal to number of rows of x
`ratePar`	(experimental) numeric value for punishing missing values
`weights`	numeric or vector of length equal to number of rows of x
`control`	list with arguments to vsclust algorithms (now only cutoff for relative tolerance: reltol)

Value

list with details about clustering having the objects ‘centers‘ (positions of centroids), ‘size‘ (feature number per cluster), ‘cluster‘ (nearest cluster of each feature), ‘membership‘ matrix of membership values, ‘iter‘ (number of carried out iterations), ‘withinerror‘ (final error from optimization), ‘call‘(call of function)

Examples

```
#' # Generate some random data
data <- matrix(rnorm(seq_len(1000)), nrow=100)
# Run clustering
clres <- vsclust_algorithm(data, centers=5, m=1.5)
head(clres$membership)
```
