Package 'GenomicFeatures'

November 21, 2024

Title Query the gene models of a given organism/assembly

Description Extract the genomic locations of genes, transcripts, exons, introns, and CDS, for the gene models stored in a TxDb object. A TxDb object is a small database that contains the gene models of a given organism/assembly. Bioconductor provides a small collection of TxDb objects in the form of ready-to-install TxDb packages for the most commonly studied organisms. Additionally, the user can easily make a TxDb object (or package) for the organism/assembly of their choice by using the tools from the txdbmaker package.

as-format-methods   *Coerce to file format structures*

Description

These functions coerce a TxDb object to a GRanges object with metadata columns encoding transcript structures according to the model of a standard file format. Currently, BED and GFF models are supported. If a TxDb is passed to export, when targeting a BED or GFF file, this coercion occurs automatically.

Usage

```
## S4 method for signature 'TxDb'
asBED(x)
## S4 method for signature 'TxDb'
asGFF(x)
```

Arguments

x   A TxDb object to coerce to a GRanges, structured as BED or GFF.

Value

For asBED, a GRanges, with the columns name, thickStart, thickEnd, blockStarts, blockSizes added. The thick regions correspond to the CDS regions, and the blocks represent the exons. The transcript IDs are stored in the name column. The ranges are the transcript bounds.

For asGFF, a GRanges, with columns type, Name, ID,, and Parent. The gene structures are expressed according to the conventions defined by the GFF3 spec. There are elements of each type of feature: "gene", "mRNA" "exon" and "cds". The Name column contains the gene_id for genes, tx_name for transcripts, and exons and cds regions are NA. The ID column uses gene_id and tx_id,

with the prefixes "GeneID" and "TxID" to ensure uniqueness across types. The exons and cds regions have `NA` for `ID`. The `Parent` column contains the `IDs` of the parent features. A feature may have multiple parents (the column is a `CharacterList`). Each exon belongs to one or more mRNAs, and mRNAs belong to a gene.

Michael Lawrence

Examples

```
txdb_file <- system.file("extdata", "hg19_knownGene_sample.sqlite",
                         package="GenomicFeatures")
txdb <- loadDb(txdb_file)

asBED(txdb)
asGFF(txdb)
```

---

coverageByTranscript   *Compute coverage by transcript (or CDS) of a set of ranges*

Description

coverageByTranscript computes the transcript (or CDS) coverage of a set of ranges.

pcoverageByTranscript is a version of coverageByTranscript that operates element-wise.

Usage

```
coverageByTranscript(x, transcripts, ignore.strand=FALSE)

pcoverageByTranscript(x, transcripts, ignore.strand=FALSE, ...)
```

Arguments

x   An object representing a set of ranges (typically aligned reads). GRanges,
              GRangesList, GAlignments, GAlignmentPairs, and GAlignmentsList objects
              are supported.

              More generally, for coverageByTranscript x can be any object for which
              seqinfo() and coverage() are supported (e.g. a BamFile object). Note that,
              for such objects, coverage() is expected to return an RleList object whose
              names are seqlevels(x)).

              More generally, for pcoverageByTranscript x can be any object for which
              grglist() is supported. It should have the length of transcripts or length 1.
              If the latter, it is recycled to the length of transcripts.

transcripts   A GRangesList object representing the exons of each transcript for which to
              compute coverage. For each transcript, the exons must be ordered by *ascending
              rank*, that is, by their position in the transcript. This means that, for a transcript
              located on the minus strand, the exons should typically be ordered by descending
              position on the reference genome. If transcripts was obtained with exonsBy,
              then the exons are guaranteed to be ordered by ascending rank. See ?exonsBy
              for more information.

Alternatively, transcripts can be a [TxDb](#) object, or any [TxDb](#)-like object that supports the [exonsBy](#)() extractor (e.g. an [EnsDb](#) object). In this case it is replaced with the [GRangesList](#) object returned by [exonsBy](#)(transcripts, by="tx", use.names=TRUE).

For pcoverageByTranscript, transcripts should have the length of x or length 1. If the latter, it is recycled to the length of x.

ignore.strand   TRUE or FALSE. If FALSE (the default) then the strand of a range in x and exon in transcripts must be the same in order for the range to contribute coverage to the exon. If TRUE then the strand is ignored.

...   Additional arguments passed to the internal call to [grglist](#)(). More precisely, when x is not a [GRanges](#) or [GRangesList](#) object, pcoverageByTranscript replace it with the [GRangesList](#) object returned by [grglist](#)(x, ...).

Value

An [RleList](#) object *parallel* to transcripts, that is, the i-th element in it is an integer-[Rle](#) representing the coverage of the i-th transcript in transcripts. Its lengths() is guaranteed to be identical to sum(width(transcripts)). The names and metadata columns on transcripts are propagated to it.

- [findCompatibleOverlaps](#) in the **GenomicAlignments** package for finding which reads are *compatible* with the splicing of which transcript.

Examples

```
## ---------------------------------------------------------------------
## 1. A SIMPLE ARTIFICIAL EXAMPLE WITH ONLY ONE TRANSCRIPT
## ---------------------------------------------------------------------

## Get some transcripts:
library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
dm3_transcripts <- exonsBy(txdb, by="tx", use.names=TRUE)
dm3_transcripts
```

```
## Let's pick up the 1st transcript: FBtr0300689. It as 2 exons and 1
## intron:
my_transcript <- dm3_transcripts["FBtr0300689"]

## Let's create 3 artificial aligned reads. We represent them as a
## GRanges object of length 3 that contains the genomic positions of
## the 3 reads. Note that these reads are simple alignments i.e. each
## of them can be represented with a single range. This would not be
## the case if they were junction reads.
my_reads <- GRanges(c("chr2L:7531-7630",
                      "chr2L:8101-8200",
                      "chr2L:8141-8240"))

## The coverage of the 3 reads on the reference genome is:
coverage(my_reads)

## As you can see, all the genomic positions in the 3 ranges participate
## to the coverage. This can be confirmed by comparing:
sum(coverage(my_reads))
## with:
sum(width(my_reads))
## They should always be the same.

## When computing the coverage on a transcript, only the part of the
## read that overlaps with the transcript participates to the coverage.
## Let's look at the individual coverage of each read on transcript
## FBtr0300689:

## The 1st read is fully contained within the 1st exon:
coverageByTranscript(my_reads[1], my_transcript)

## Note that the length of the Rle (1880) is the length of the transcript.

## The 2nd and 3rd reads overlap the 2 exons and the intron. Only the
## parts that overlap the exons participate to coverage:
coverageByTranscript(my_reads[2], my_transcript)
coverageByTranscript(my_reads[3], my_transcript)

## The coverage of the 3 reads together is:
coverageByTranscript(my_reads, my_transcript)

## Note that this is the sum of the individual coverages. This can be
## checked with:
stopifnot(all(
  coverageByTranscript(my_reads, my_transcript)
  ==
  Reduce("+", lapply(seq_along(my_reads),
      function(i) coverageByTranscript(my_reads[i], my_transcript)), 0L)
))

## ---------------------------------------------------------------------
## 2. COMPUTE THE FULL TRANSCRIPTOME COVERAGE OF A SET OF ALIGNED READS
## ---------------------------------------------------------------------

## Load the aligned reads:
library(pasillaBamSubset)
library(GenomicAlignments)
```

```
reads <- readGAlignments(untreated1_chr4())

## Compute the full transcriptome coverage by calling
## coverageByTranscript() on 'dm3_transcripts':
tx_cvg <- coverageByTranscript(reads, dm3_transcripts, ignore.strand=TRUE)
tx_cvg

## A sanity check:
stopifnot(identical(lengths(tx_cvg), sum(width(dm3_transcripts))))

## We can also use pcoverageByTranscript() to compute 'tx_cvg'.
## For this we first create a GAlignmentsList object "parallel" to
## 'dm3_transcripts' where the i-th list element contains the aligned
## reads that overlap with the i-th transcript:
hits <- findOverlaps(reads, dm3_transcripts, ignore.strand=TRUE)
tx2reads <- setNames(as(t(hits), "List"), names(dm3_transcripts))
reads_by_tx <- extractList(reads, tx2reads)  # GAlignmentsList object
reads_by_tx

## Call pcoverageByTranscript():
tx_cvg2 <- pcoverageByTranscript(reads_by_tx, dm3_transcripts,
                                 ignore.strand=TRUE)
stopifnot(identical(tx_cvg, tx_cvg2))

## A more meaningful coverage is obtained by counting for each
## transcript only the reads that are *compatible* with its splicing:
compat_hits <- findCompatibleOverlaps(reads, dm3_transcripts)
tx2reads <- setNames(as(t(compat_hits), "List"), names(dm3_transcripts))
compat_reads_by_tx <- extractList(reads, tx2reads)

tx_compat_cvg <- pcoverageByTranscript(compat_reads_by_tx,
                                       dm3_transcripts,
                                       ignore.strand=TRUE)
## A sanity check:
stopifnot(all(all(tx_compat_cvg <= tx_cvg)))

## ---------------------------------------------------------------------
## 3. COMPUTE CDS COVERAGE OF A SET OF ALIGNED READS
## ---------------------------------------------------------------------

## coverageByTranscript() can also be used to compute CDS coverage:
cds <- cdsBy(txdb, by="tx", use.names=TRUE)
cds_cvg <- coverageByTranscript(reads, cds, ignore.strand=TRUE)
cds_cvg

## A sanity check:
stopifnot(identical(lengths(cds_cvg), sum(width(cds))))

## ---------------------------------------------------------------------
## 4. ALTERNATIVELY, THE CDS COVERAGE CAN BE OBTAINED FROM THE
##    TRANSCRIPT COVERAGE BY TRIMMING THE 5' AND 3' UTRS
## ---------------------------------------------------------------------

tx_lens <- transcriptLengths(txdb, with.utr5_len=TRUE, with.utr3_len=TRUE)
stopifnot(identical(tx_lens$tx_name, names(tx_cvg)))  # sanity

## Keep the rows in 'tx_lens' that correspond to a list element in
```

```
## 'cds_cvg' and put them in the same order as in 'cds_cvg':
m <- match(names(cds_cvg), names(tx_cvg))
tx_lens <- tx_lens[m, ]
utr5_width <- tx_lens$utr5_len
utr3_width <- tx_lens$utr3_len
cds_cvg2 <- windows(tx_cvg[m], start=1L+utr5_width, end=-1L-utr3_width)

## A sanity check:
stopifnot(identical(cds_cvg2, cds_cvg))
```

---

exonicParts   *Extract non-overlapping exonic or intronic parts from a TxDb-like ob-*
                          ject

Description

exonicParts and intronicParts extract the non-overlapping (a.k.a. disjoint) exonic or intronic
parts from a TxDb-like object.

Usage

```
exonicParts(txdb, linked.to.single.gene.only=FALSE)
intronicParts(txdb, linked.to.single.gene.only=FALSE)

## 3 helper functions used internally by exonicParts() and intronicParts():
tidyTranscripts(txdb, drop.geneless=FALSE)
tidyExons(txdb, drop.geneless=FALSE)
tidyIntrons(txdb, drop.geneless=FALSE)
```

Arguments

txdb   A TxDb object, or any TxDb-like object that supports the transcripts() and
                            exonsBy() extractors (e.g. an EnsDb object).

linked.to.single.gene.only
                            TRUE or FALSE.

                            If FALSE (the default), then the disjoint parts are obtained by calling disjoin()
                            on all the exons (or introns) in txdb, including on exons (or introns) not linked
                            to a gene or linked to more than one gene.

                            If TRUE, then the disjoint parts are obtained in 2 steps:

                            1. call disjoin() on the exons (or introns) linked to *at least one gene*,
                            2. then drop the parts linked to more than one gene from the set of exonic (or
                               intronic) parts obtained previously.

drop.geneless   If FALSE (the default), then all the transcripts (or exons, or introns) get extracted
                            from the TxDb object.

                            If TRUE, then only the transcripts (or exons, or introns) that are linked to a gene
                            get extracted from the TxDb object.

                            Note that drop.geneless also impacts the order in which the features are re-
                            turned:
```

- Transcripts: If drop.geneless is FALSE then transcripts are returned in the same order as with [transcripts](), which is expected to be by internal transcript id (tx_id). Otherwise they are ordered first by gene id (gene_id), then by internal transcript id.
- Exons: If drop.geneless is FALSE then exons are ordered first by internal transcript id (tx_id), then by exon rank (exon_rank). Otherwise they are ordered first by gene id (gene_id), then by internal transcript id, and then by exon rank.
- Introns: If drop.geneless is FALSE then introns are ordered by internal transcript id (tx_id). Otherwise they are ordered first by gene id (gene_id), then by internal transcript id.

**Value**

exonicParts returns a disjoint and strictly sorted [GRanges]() object with 1 range per exonic part and with metadata columns tx_id, tx_name, gene_id, exon_id, exon_name, and exon_rank. If linked.to.single.gene.only was set to TRUE, an additional exonic_part metadata column is added that indicates the rank of each exonic part within all the exonic parts linked to the same gene.

intronicParts returns a disjoint and strictly sorted [GRanges]() object with 1 range per intronic part and with metadata columns tx_id, tx_name, and gene_id. If linked.to.single.gene.only was set to TRUE, an additional intronic_part metadata column is added that indicates the rank of each intronic part within all the intronic parts linked to the same gene.

tidyTranscripts returns a [GRanges]() object with 1 range per transcript and with metadata columns tx_id, tx_name, and gene_id.

tidyExons returns a [GRanges]() object with 1 range per exon and with metadata columns tx_id, tx_name, gene_id, exon_id, exon_name, and exon_rank.

tidyIntrons returns a [GRanges]() object with 1 range per intron and with metadata columns tx_id, tx_name, and gene_id.

```

---

extendExonsIntoIntrons

Extend exons by a given number of bases into their adjacent introns

---

Description

extendExonsIntoIntrons extends the supplied exons by a given number of bases into their adjacent introns.

Usage

```
extendExonsIntoIntrons(ex_by_tx, extent=2)
```

Arguments

ex_by_tx   A [GRangesList](#) object containing exons grouped by transcript. This must be an
              object as returned by [exonsBy](#)(txdb, by="tx"), that is:

              • each list element in ex_by_tx must be a [GRanges](#) object representing the
                exons of a given transcript;
              • the exons in each list element must be ordered by ascending rank with re-
                spect to their transcript.

extent   Size of the extent in number of bases. 2 by default.

              The first exon in a transcript will be extended by that amount on its 3' side only.
              The last exon in a transcript will be extended by that amount on its 5' side only.
              All other exons (i.e. intermediate exons) will be extended by that amount on
              each side.

Note that exons that belong to a single-exon transcript don't get extended.

The default value of 2 corresponds to inclusion of the donor/acceptor intronic regions (typically GT/AG).

Value

A copy of [GRangesList](#) object ex_by_tx where the original exon ranges have been extended.

Names and metadata columns on ex_by_tx are propagated to the result.

- [exonicParts](#) and [intronicParts](#) for extracting non-overlapping exonic or intronic parts from a TxDb-like object.

- [extractTranscriptSeqs](#) for extracting transcript (or CDS) sequences from chromosome sequences.

- The [TxDb](#) class.

Examples

```
## With toy transcripts:
ex_by_tx <- GRangesList(
    TX1="chr1:10-20:+",
    TX2=c("chr1:10-20:+", "chr1:50-75:+"),
    TX3=c("chr1:10-20:+", "chr1:50-75:+", "chr1:100-120:+"),
    TX4="chr1:10-20:-",
    TX5=c("chr1:10-20:-", "chr1:50-75:-"),
    TX6=c("chr1:10-20:-", "chr1:50-75:-", "chr1:100-120:-")
)

extended <- extendExonsIntoIntrons(ex_by_tx, extent=2)
extended[1:3]
extended[4:6]

## With real-world transcripts:
library(TxDb.Celegans.UCSC.ce11.ensGene)
txdb <- TxDb.Celegans.UCSC.ce11.ensGene
ex_by_tx <- exonsBy(txdb, by="tx")
ex_by_tx

extendExonsIntoIntrons(ex_by_tx, extent=2)

## Sanity check:
stopifnot(identical(extendExonsIntoIntrons(ex_by_tx, extent=0), ex_by_tx))
```

extractTranscriptSeqs   *Extract transcript (or CDS) sequences from chromosome sequences*

Description

extractTranscriptSeqs extracts transcript (or CDS) sequences from an object representing a single chromosome or a collection of chromosomes.

Usage

```
extractTranscriptSeqs(x, transcripts, ...)

## S4 method for signature 'DNAString'
extractTranscriptSeqs(x, transcripts, strand="+")

## S4 method for signature 'ANY'
extractTranscriptSeqs(x, transcripts, ...)
```

Arguments

x
: An object representing a single chromosome or a collection of chromosomes. More precisely, x can be a [DNAString](#) object (single chromosome), or a [BSgenome](#) object (collection of chromosomes).

  Other objects representing a collection of chromosomes are supported (e.g. [FaFile](#) objects in the **Rsamtools** package) as long as [seqinfo](#) and [getSeq](#) work on them.

transcripts
: An object representing the exon ranges of each transcript to extract. More precisely:

  - If x is a [DNAString](#) object, then transcripts must be an [IntegerRanges-List](#) object.
  - If x is a [BSgenome](#) object or any object representing a collection of chromosomes, then transcripts must be a [GRangesList](#) object or any object for which [exonsBy](#) is implemented (e.g. a [TxDb](#) or [EnsDb](#) object). If the latter, then it's first turned into a [GRangesList](#) object with [exonsBy](#)(transcripts, by="tx", ...).

  Note that, for each transcript, the exons must be ordered by ascending *rank*, that is, by ascending position *in the transcript* (when going in the 5' to 3' direction). This generally means (but not always) that they are also ordered from 5' to 3' on the reference genome. More precisely:

  - For a transcript located on the plus strand, the exons will typically (but not necessarily) be ordered by ascending position on the reference genome.
  - For a transcript located on the minus strand, the exons will typically (but not necessarily) be ordered by descending position on the reference genome.

  If transcripts was obtained with [exonsBy](#) (see above), then the exons are guaranteed to be ordered by ascending rank. See ?[exonsBy](#) for more information.

...
: Additional arguments, for use in specific methods.

  For the default method, additional arguments are allowed only when transcripts is not a [GRangesList](#) object, in which case they are passed to the internal call to [exonsBy](#) (see above).

strand   Only supported when x is a [DNAString](#) object.

                  Can be an atomic vector, a factor, or an [Rle](#) object, in which case it indicates the
                  strand of each transcript (i.e. all the exons in a transcript are considered to be
                  on the same strand). More precisely: it's turned into a factor (or factor-[Rle](#)) that
                  has the "standard strand levels" (this is done by calling the [strand](#) function on
                  it). Then it's recycled to the length of [IntegerRangesList](#) object transcripts if
                  needed. In the resulting object, the i-th element is interpreted as the strand of all
                  the exons in the i-th transcript.

                  strand can also be a list-like object, in which case it indicates the strand of
                  each exon, individually. Thus it must have the same *shape* as [IntegerRangesList](#)
                  object transcripts (i.e. same length plus strand[[i]] must have the same
                  length as transcripts[[i]] for all i).

                  strand can only contain "+" and/or "-" values. "*" is not allowed.

Value

A [DNAStringSet](#) object *parallel* to transcripts, that is, the i-th element in it is the sequence of
the i-th transcript in transcripts.

  age.
- The [translate](#) function in the **Biostrings** package for translating DNA or RNA sequences
  into amino acid sequences.
- The [GRangesList](#) class defined and documented in the **GenomicRanges** package.
- The [IntegerRangesList](#) class defined and documented in the **IRanges** package.
- The [exonsBy](#) function for extracting exon ranges grouped by transcript.
- The [TxDb](#) class.

Examples

```
## ---------------------------------------------------------------------
## 1. A TOY EXAMPLE
## ---------------------------------------------------------------------

library(Biostrings)
```

```
## A chromosome of length 30:
x <- DNAString("ATTTAGGACACTCCCTGAGGACAAGACCCC")

## 2 transcripts on 'x':
tx1 <- IRanges(1, 8)            # 1 exon
tx2 <- c(tx1, IRanges(12, 30))  # 2 exons
transcripts <- IRangesList(tx1=tx1, tx2=tx2)
extractTranscriptSeqs(x, transcripts)

## By default, all the exons are considered to be on the plus strand.
## We can use the 'strand' argument to tell extractTranscriptSeqs()
## to extract them from the minus strand.

## Extract all the exons from the minus strand:
extractTranscriptSeqs(x, transcripts, strand="-")

## Note that, for a transcript located on the minus strand, the exons
## should typically be ordered by descending position on the reference
## genome in order to reflect their rank in the transcript:
extractTranscriptSeqs(x, IRangesList(tx1=tx1, tx2=rev(tx2)), strand="-")

## Extract the exon of the 1st transcript from the minus strand:
extractTranscriptSeqs(x, transcripts, strand=c("-", "+"))

## Extract the 2nd exon of the 2nd transcript from the minus strand:
extractTranscriptSeqs(x, transcripts, strand=list("-", c("+", "-")))

## ---------------------------------------------------------------------
## 2. A REAL EXAMPLE
## ---------------------------------------------------------------------

## Load a genome:
library(BSgenome.Hsapiens.UCSC.hg19)
genome <- BSgenome.Hsapiens.UCSC.hg19

## Load a TxDb object:
txdb_file <- system.file("extdata", "hg19_knownGene_sample.sqlite",
                          package="GenomicFeatures")
txdb <- loadDb(txdb_file)

## Check that 'txdb' is based on the hg19 assembly:
txdb

## Extract the exon ranges grouped by transcript from 'txdb':
transcripts <- exonsBy(txdb, by="tx", use.names=TRUE)

## Extract the transcript sequences from the genome:
tx_seqs <- extractTranscriptSeqs(genome, transcripts)
tx_seqs

## A sanity check:
stopifnot(identical(width(tx_seqs), unname(sum(width(transcripts)))))

## Note that 'tx_seqs' can also be obtained with:
extractTranscriptSeqs(genome, txdb, use.names=TRUE)

## ---------------------------------------------------------------------
```

```
## 3. USING extractTranscriptSeqs() TO EXTRACT CDS SEQUENCES
## --------------------------------------------------------------

cds <- cdsBy(txdb, by="tx", use.names=TRUE)
cds_seqs <- extractTranscriptSeqs(genome, cds)
cds_seqs

## A sanity check:
stopifnot(identical(width(cds_seqs), unname(sum(width(cds)))))

## Note that, alternatively, the CDS sequences can be obtained from the
## transcript sequences by removing the 5' and 3' UTRs:
tx_lens <- transcriptLengths(txdb, with.utr5_len=TRUE, with.utr3_len=TRUE)
stopifnot(identical(tx_lens$tx_name, names(tx_seqs)))  # sanity
## Keep the rows in 'tx_lens' that correspond to a sequence in 'cds_seqs'
## and put them in the same order as in 'cds_seqs':
m <- match(names(cds_seqs), names(tx_seqs))
tx_lens <- tx_lens[m, ]
utr5_width <- tx_lens$utr5_len
utr3_width <- tx_lens$utr3_len
cds_seqs2 <- narrow(tx_seqs[m],
                    start=utr5_width+1L, end=-(utr3_width+1L))
stopifnot(identical(as.character(cds_seqs2), as.character(cds_seqs)))

## --------------------------------------------------------------
## 4. TRANSLATE THE CDS SEQUENCES
## --------------------------------------------------------------

prot_seqs <- translate(cds_seqs, if.fuzzy.codon="solve")

## Note that, by default, translate() uses The Standard Genetic Code to
## translate codons into amino acids. However, depending on the organism,
## a different genetic code might be needed to translate CDS sequences
## located on the mitochodrial chromosome. For example, for vertebrates,
## the following code could be used to correct 'prot_seqs':
SGC1 <- getGeneticCode("SGC1")
chrM_idx <- which(all(seqnames(cds) == "chrM"))
prot_seqs[chrM_idx] <- translate(cds_seqs[chrM_idx], genetic.code=SGC1,
                                 if.fuzzy.codon="solve")
```

---

extractUpstreamSeqs   *Extract sequences upstream of a set of genes or transcripts*

Description

extractUpstreamSeqs is a generic function for extracting sequences upstream of a supplied set of genes or transcripts.

Usage

```
extractUpstreamSeqs(x, genes, width=1000, ...)

## Dispatch is on the 2nd argument!
```

```
## S4 method for signature 'GenomicRanges'
extractUpstreamSeqs(x, genes, width=1000)

## S4 method for signature 'TxDb'
extractUpstreamSeqs(x, genes, width=1000, exclude.seqlevels=NULL)
```

Arguments

x   An object containing the chromosome sequences from which to extract the up-
            stream sequences. It can be a [BSgenome](#), [TwoBitFile](#), or [FaFile](#) object, or any
            genome sequence container. More formally, x must be an object for which
            [seqinfo](#) and [getSeq](#) are defined.

genes   An object containing the locations (i.e. chromosome name, start, end, and
            strand) of the genes or transcripts with respect to the reference genome. Only
            [GenomicRanges](#) and [TxDb](#) objects are supported at the moment. If the latter, the
            gene locations are obtained by calling the [genes](#) function on the [TxDb](#) object
            internally.

width   How many bases to extract upstream of each TSS (transcription start site).

...   Additional arguments, for use in specific methods.

exclude.seqlevels
            A character vector containing the chromosome names (a.k.a. sequence levels)
            to exclude when the genes are obtained from a [TxDb](#) object.

Value

A [DNAStringSet](#) object containing one upstream sequence per gene (or per transcript if genes is a
[GenomicRanges](#) object containing transcript ranges).

More precisely, if genes is a [GenomicRanges](#) object, the returned object is *parallel* to it, that is,
the i-th element in the returned object is the upstream sequence corresponding to the i-th gene (or
transcript) in genes. Also the names on the [GenomicRanges](#) object are propagated to the returned
object.

If genes is a [TxDb](#) object, the names on the returned object are the gene IDs found in the [TxDb](#)
object. To see the type of gene IDs (i.e. Entrez gene ID or Ensembl gene ID or ...), you can display
genes with show(genes).

In addition, the returned object has the following metadata columns (accessible with [mcols](#)) that
provide some information about the gene (or transcript) corresponding to each upstream sequence:

- gene_seqnames: the chromosome name of the gene (or transcript);
- gene_strand: the strand of the gene (or transcript);
- gene_TSS: the transcription start site of the gene (or transcript).

Note

IMPORTANT: Always make sure to use a TxDb package (or [TxDb](#) object) that contains a gene
model compatible with the *genome sequence container* x, that is, a gene model based on the exact
same reference genome as x.

See http://bioconductor.org/packages/release/BiocViews.html#___TxDb for the list of
TxDb packages available in the current release of Bioconductor. Note that you can make your
own custom [TxDb](#) object from various annotation resources by using one of the makeTxDbFrom*()
functions listed in the "See also" section below.

- makeTxDbFromUCSC, makeTxDbFromBiomart, and makeTxDbFromEnsembl, for making a TxDb object from online resources.

- makeTxDbFromGRanges and makeTxDbFromGFF for making a TxDb object from a GRanges object, or from a GFF or GTF file.

- The available.genomes function in the **BSgenome** package for checking avaibility of BSgenome data packages (and installing the desired one).

- The BSgenome, TwoBitFile, and FaFile classes, defined and documented in the **BSgenome**, **rtracklayer**, and **Rsamtools** packages, respectively.

- The TxDb class.

- The genes function for extracting gene ranges from a TxDb object.

- The GenomicRanges class defined and documented in the **GenomicRanges** package.

- The DNAStringSet class defined and documented in the **Biostrings** package.

- The seqinfo getter defined and documented in the **GenomeInfoDb** package.

- The getSeq function for extracting subsequences from a sequence container.

Examples

```
## Load a genome:
library(BSgenome.Dmelanogaster.UCSC.dm3)
genome <- BSgenome.Dmelanogaster.UCSC.dm3
genome

## Use a TxDb object:
library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
txdb  # contains Ensembl gene IDs

## Because the chrU and chrUextra sequences are made of concatenated
## scaffolds (see https://genome.ucsc.edu/cgi-bin/hgGateway?db=dm3),
## extracting the upstream sequences for genes located on these
## scaffolds is not reliable. So we exclude them:
exclude <- c("chrU", "chrUextra")
up1000seqs <- extractUpstreamSeqs(genome, txdb, width=1000,
                                  exclude.seqlevels=exclude)
up1000seqs  # the names are Ensembl gene IDs
mcols(up1000seqs)

## Upstream sequences for genes close to the chromosome bounds can be
## shorter than 1000 (note that this does not happen for circular
## chromosomes like chrM):
table(width(up1000seqs))
mcols(up1000seqs)[width(up1000seqs) != 1000, ]
```

FeatureDb-class *FeatureDb objects*

Description

WARNING: The FeatureDb/makeFeatureDbFromUCSC/features code base is no longer actively maintained and FeatureDb-related functionalities might get deprecated in the near future. Please use makeFeatureDbFromUCSC for a convenient way to import transcript annotations from UCSC online resources into Bioconductor.

The FeatureDb class is a generic container for storing genomic locations of an arbitrary type of genomic features.

See ?TxDb for a container for storing transcript annotations.

See ?makeFeatureDbFromUCSC for a convenient way to make FeatureDb objects from BioMart online resources.

Methods

In the code snippets below, x is a FeatureDb object.

metadata(x): Return x's metadata in a data frame.

Author(s)

Marc Carlson

- The TxDb class for storing transcript annotations.

- makeFeatureDbFromUCSC for a convenient way to make a FeatureDb object from UCSC online resources.

- saveDb and loadDb for saving and loading the database content of a FeatureDb object.

- features for how to extract genomic features from a FeatureDb object.

Examples

```
fdb_file <- system.file("extdata", "FeatureDb.sqlite",
                        package="GenomicFeatures")
fdb <- loadDb(fdb_file)
fdb
```

---

features   *Extract simple features from a FeatureDb object*

Description

WARNING: The FeatureDb/makeFeatureDbFromUCSC/features code base is no longer actively
maintained and FeatureDb-related functionalities might get deprecated in the near future. Please
use `makeFeatureDbFromUCSC` for a convenient way to import transcript annotations from UCSC
online resources into Bioconductor.

Generic function to extract genomic features from a FeatureDb object.

Usage

```
features(x)
## S4 method for signature 'FeatureDb'
features(x)
```

Arguments

x   A FeatureDb object.

Value

a GRanges object

Author(s)

M. Carlson

See Also

FeatureDb

Examples

```
fdb <- loadDb(system.file("extdata", "FeatureDb.sqlite",
                                package="GenomicFeatures"))
features(fdb)
```

---

getPromoterSeq   *Get gene promoter or terminator sequences*

Description

Extract promoter or terminator sequences for the genes or transcripts specified in the query (aGRanges
or GRangesList object) from a BSgenome or FaFile object.

Usage

```
## S4 method for signature 'GRanges'
getPromoterSeq(query, subject, upstream=2000, downstream=200)
## S4 method for signature 'GRanges'
getTerminatorSeq(query, subject, upstream=2000, downstream=200)

## S4 method for signature 'GRangesList'
getPromoterSeq(query, subject, upstream=2000, downstream=200)
## S4 method for signature 'GRangesList'
getTerminatorSeq(query, subject, upstream=2000, downstream=200)
```

Arguments

query	A GRanges or GRangesList object containing genes grouped by transcript.
subject	A BSgenome or FaFile object from which the sequences will be taken.
upstream	The number of DNA bases to include upstream of the TSS (transcription start site)
downstream	The number of DNA bases to include downstream of the TSS (transcription start site)

Details

getPromoterSeq and getTerminatorSeq are generic functions dispatching on query, which is either a GRanges or a GRangesList. They are convenience wrappers for the promoters, terminators, and getSeq functions. The purpose is to allow sequence extraction from either a BSgenome or FaFile object.

Default values for upstream and downstream were chosen based on our current understanding of gene regulation. On average, promoter regions in the mammalian genome are 5000 bp upstream and downstream of the transcription start site.

Value

A DNAStringSet or DNAStringSetList instance corresponding to the GRanges or GRangesList supplied in the query.

Author(s)

Paul Shannon

See Also

- The promoters man page in the **GenomicRanges** package for the promoters() and terminators() methods for GenomicRanges objects.
- getSeq in the **Biostrings** package for extracting a set of sequences from a sequence container like a BSgenome or FaFile object.

Examples

```
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
library(BSgenome.Hsapiens.UCSC.hg19)
```

```
## A GRangesList object describing all the known Human transcripts grouped
## by gene:
txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
tx_by_gene <- transcriptsBy(txdb, by="gene")

e2f3 <- "1871"  # entrez geneID for a cell cycle control transcription
                # factor, chr6 on the plus strand

## A GRanges object describing the three transcripts for gene 1871:
e2f3_tx <- tx_by_gene[[e2f3]]

## Promoter sequences for gene 1871:
e2f3_promoter_seqs <- getPromoterSeq(e2f3_tx, Hsapiens,
                                     upstream=40, downstream=15)
e2f3_promoter_seqs

mcols(e2f3_promoter_seqs)

## Terminator sequences for gene 1871:
e2f3_terminator_seqs <- getTerminatorSeq(e2f3_tx, Hsapiens,
                                         upstream=25, downstream=10)

e2f3_terminator_seqs

mcols(e2f3_terminator_seqs)  # same as 'mcols(e2f3_promoter_seqs)'

## All Human promoter sequences grouped by gene:
getPromoterSeq(tx_by_gene, Hsapiens, upstream=6, downstream=4)
```

---

id2name   *Map internal ids to external names for a given feature type*

Description

Utility function for retrieving the mapping from the internal ids to the external names of a given
feature type.

Usage

```
id2name(txdb, feature.type=c("tx", "exon", "cds"))
```

Arguments

txdb   A TxDb object.

feature.type   The feature type for which the mapping must be retrieved.

Details

Transcripts, exons and CDS parts in a TxDb object are stored in seperate tables where the primary
key is an integer called *feature internal id*. This id is stored in the "tx_id" column for transcripts,
in the "exon_id" column for exons, and in the "cds_id" column for CDS parts. Unlike other
commonly used ids like Entrez Gene IDs or Ensembl IDs, this internal id was generated at the time
the TxDb object was created and has no meaning outside the scope of this object.

The id2name function can be used to translate this internal id into a more informative id or name called *feature external name*. This name is stored in the "tx_name" column for transcripts, in the "exon_name" column for exons, and in the "cds_name" column for CDS parts.

Note that, unlike the feature internal id, the feature external name is not guaranteed to be unique or even defined (the column can contain NAs).

Value

A named character vector where the names are the internal ids and the values the external names.

in the **txdbmaker** package.

mapIdsToRanges	*Map IDs to Genomic Ranges*

Description

Map IDs to Genomic Ranges

Usage

```
mapIdsToRanges(x, ...)

## S4 method for signature 'TxDb'
mapIdsToRanges(x, keys, type = c("cds", "exon", "tx",
  "gene"), columns = NULL)
```

Arguments

x	Database to use for mapping
keys	Values to lookup, passed to transcripts et. al.
type	Types of feature to return
columns	Additional metadata columns to include in the output
...	Additional arguments passed to methods

Value

GRangesList corresponding to the keys

Methods (by class)

- TxDb: TxDb method

Examples

```
fl <- system.file(package = "GenomicFeatures", "extdata", "sample_ranges.rds")
txdb <- makeTxDbFromGRanges(readRDS(fl))

keys <- list(tx_name = c("ENST00000371582", "ENST00000371588",
    "ENST00000494752", "ENST00000614008", "ENST00000496771"))
mapIdsToRanges(txdb, keys = keys, type = "tx")
```

---

mapRangesToIds *Map Genomic Ranges to IDs*

Description

Map Genomic Ranges to IDs

Usage

```
mapRangesToIds(x, ...)

## S4 method for signature 'TxDb'
mapRangesToIds(x, ranges, type = c("cds", "exon", "tx",
  "gene"), columns = NULL, ...)
```

Arguments

x	Database to use for mapping
ranges	range object used to subset
type	of feature to return
columns	additional metadata columns to include in the output.
...	Additional arguments passed to findOverlaps

Value

DataFrame of mcols from the database.

Methods (by class)

- TxDb: TxDb method

Examples

```
fl <- system.file(package = "GenomicFeatures", "extdata", "sample_ranges.rds")
txdb <- makeTxDbFromGRanges(readRDS(fl))

keys <- list(tx_name = c("ENST00000371582", "ENST00000371588",
    "ENST00000494752", "ENST00000614008", "ENST00000496771"))
res <- mapIdsToRanges(txdb, keys = keys, type = "tx")
mapRangesToIds(txdb, res, "tx")
```

---

mapToTranscripts   *Map range coordinates between transcripts and genome space*

Description

Map range coordinates between features in the transcriptome and genome (reference) space.

See ?mapToAlignments in the **GenomicAlignments** package for mapping coordinates between reads (local) and genome (reference) space using a CIGAR alignment.

Usage

```
## mapping to transcripts
## S4 method for signature 'GenomicRanges,GenomicRanges'
mapToTranscripts(x, transcripts,
          ignore.strand = FALSE)
## S4 method for signature 'GenomicRanges,GRangesList'
mapToTranscripts(x, transcripts,
          ignore.strand = FALSE, intronJunctions=FALSE)
## S4 method for signature 'ANY,TxDb'
mapToTranscripts(x, transcripts, ignore.strand = FALSE,
          extractor.fun = GenomicFeatures::transcripts, ...)
## S4 method for signature 'GenomicRanges,GRangesList'
pmapToTranscripts(x, transcripts,
          ignore.strand = FALSE)

## mapping from transcripts
## S4 method for signature 'GenomicRanges,GRangesList'
mapFromTranscripts(x, transcripts,
          ignore.strand = FALSE)
## S4 method for signature 'GenomicRanges,GRangesList'
pmapFromTranscripts(x, transcripts,
          ignore.strand = FALSE)
## S4 method for signature 'IntegerRanges,GRangesList'
pmapFromTranscripts(x, transcripts)
```

Arguments

x	GenomicRanges object of positions to be mapped. The seqnames of x are used in mapFromTranscripts, i.e., when mapping from transcripts to the genome. In the case of pmapFromTranscripts, x can be an IntegerRanges object.
transcripts	A named GenomicRanges or GRangesList object used to map between x and the result. The ranges can be any feature in the transcriptome extracted from a TxDb (e.g., introns, exons, CDS parts). See ?transcripts and ?transcriptsBy for a list of extractor functions.
	The transcripts object must have names. When mapping from transcripts to the genome, they are used to determine mapping pairs; in the reverse direction they become the seqlevels of the output object.
ignore.strand	When ignore.strand is TRUE, strand is ignored in overlaps operations (i.e., all strands are considered "+") and the strand in the output is '*'.

When `ignore.strand` is FALSE strand in the output is taken from the `transcripts` argument. When `transcripts` is a GRangesList, all inner list elements of a common list element must have the same strand or an error is thrown.

Mapped position is computed by counting from the transcription start site (TSS) and is not affected by the value of `ignore.strand`.

intronJunctions

Logical to indicate if intronic ranges in `x` should be reported.

This argument is only supported in `mapToTranscripts` when `transcripts` is a GRangesList. When `transcripts` is a GRangesList, individual ranges can be thought of as exons and the spaces between the ranges as introns.

When `intronJunctions=TRUE`, ranges that fall completely "within" an intron are reported as a zero-width range (start and end are taken from the ranges they fall between). A metadata column called "intronic" is returned with the GRanges and marked as `TRUE` for these ranges. By default, `intronJunctions=FALSE` and these ranges are not mapped.

Ranges that have either the start or end in an intron are considered "non hits" and are never mapped. Ranges that span introns are always mapped. Neither of these range types are controlled by the `intronJunctions` argument.

extractor.fun   Function to extract genomic features from a `TxDb` object.

This argument is only applicable to `mapToTranscripts` when `transcripts` is a `TxDb` object. The `extractor` should be the name of a function (not a character()) described on the ?`transcripts`, ?`transcriptsBy`, or ?`microRNAs` man page.

Valid `extractor` functions:

- transcripts ## default
- exons
- cds
- genes
- promoters
- exonicParts
- intronicParts
- transcriptsBy
- exonsBy
- cdsBy
- intronsByTranscript
- fiveUTRsByTranscript
- threeUTRsByTranscript
- microRNAs
- tRNAs

...   Additional arguments passed to `extractor.fun` functions.

Details

In GenomicFeatures >= 1.21.10, the default for `ignore.strand` was changed to FALSE for consistency with other methods in the **GenomicRanges** and **GenomicAlignments** packages. Additionally, the mapped position is computed from the TSS and does not depend on the `ignore.strand` argument. See the section on `ignore.strand` for details.

- mapToTranscripts, pmapToTranscripts The genomic range in `x` is mapped to the local position in the `transcripts` ranges. A successful mapping occurs when `x` is completely within the `transcripts` range, equivalent to:

```
findOverlaps(..., type="within")
```

Transcriptome-based coordinates start counting at 1 at the beginning of the `transcripts` range and return positions where x was aligned. The seqlevels of the return object are taken from the `transcripts` object and should be transcript names. In this direction, mapping is attempted between all elements of x and all elements of `transcripts`.

`mapToTranscripts` uses `findOverlaps` to map ranges in x to ranges in `transcripts`. This method does not return unmapped ranges.

`pmapToTranscripts` maps the i-th range in x to the i-th range in `transcripts`. Recycling is supported for both x and `transcripts` when either is length == 1L; otherwise the lengths must match. Ranges in x that do not map (out of bounds or strand mismatch) are returned as zero-width ranges starting at 0. These ranges are given the seqname of "UNMAPPED".

- `mapFromTranscripts`, `pmapFromTranscripts` The transcript-based position in x is mapped to genomic coordinates using the ranges in `transcripts`. A successful mapping occurs when the following is TRUE:

```
width(transcripts) >= start(x) + width(x)
```

x is aligned to `transcripts` by moving in `start(x)` positions in from the beginning of the `transcripts` range. The seqlevels of the return object are chromosome names.

`mapFromTranscripts` uses the seqname of x and the names of `transcripts` to determine mapping pairs (vs attempting to match all possible pairs). Name matching is motivated by use cases such as differentially expressed regions where the expressed regions in x would only be related to a subset of regions in `transcripts`. This method does not return unmapped ranges.

`pmapFromTranscripts` maps the i-th range in x to the i-th range in `transcripts` and therefore does not use name matching. Recycling is supported in `pmapFromTranscripts` when either x or `transcripts` is length == 1L; otherwise the lengths must match. Ranges in x that do not map (out of bounds or strand mismatch) are returned as zero-width ranges starting at 0. These ranges are given the seqname of "UNMAPPED".

Value

`pmapToTranscripts` returns a `GRanges` the same length as x.

`pmapFromTranscripts` returns a `GRanges` when `transcripts` is a `GRanges` and a `GRangesList` when `transcripts` is a `GRangesList`. In both cases the return object is the same length as x. The rational for returning the `GRangesList` is to preserve exon structure; ranges in a list element that are not overlapped by x are returned as a zero-width range. The `GRangesList` return object will have no seqlevels called "UNMAPPED"; those will only occur when a `GRanges` is returned.

`mapToTranscripts` and `mapFromTranscripts` return `GRanges` objects that vary in length similar to a `Hits` object. The result contains mapped records only; strand mismatch and out of bound ranges are not returned. `xHits` and `transcriptsHits` metadata columns (similar to the `queryHits` and `subjectHits` of a `Hits` object) indicate elements of x and `transcripts` used in the mapping.

When `intronJunctions` is TRUE, `mapToTranscripts` returns an extra metdata column named `intronic` to identify the intron ranges.

When mapping to transcript coordinates, seqlevels of the output are the names on the `transcripts` object and most often these will be transcript names. When mapping to the genome, seqlevels of the output are the seqlevels of `transcripts` which are usually chromosome names.

## ----------------------------------------------------------------------
## B. Map sequence locations in exons to the genome
## ----------------------------------------------------------------------

## NAGNAG alternative splicing plays an essential role in biological
## processes and represents a highly adaptable system for
## posttranslational regulation of gene function. The majority of
## NAGNAG studies largely focus on messenger RNA. A study by Sun,
## Lin, and Yan (http://www.hindawi.com/journals/bmri/2014/736798/)
## demonstrated that NAGNAG splicing is also operative in large
## intergenic noncoding RNA (lincRNA). One finding of interest was
## that linc-POLR3G-10 exhibited two NAGNAG acceptors located in two
## distinct transcripts: TCONS_00010012 and TCONS_00010010.

## Extract the exon coordinates of TCONS_00010012 and TCONS_00010010:
lincrna <- c("TCONS_00010012", "TCONS_00010010")
library(TxDb.Hsapiens.UCSC.hg19.lincRNAsTranscripts)
txdb <- TxDb.Hsapiens.UCSC.hg19.lincRNAsTranscripts
exons <- exonsBy(txdb, by="tx", use.names=TRUE)[lincrna]
exons

## The two NAGNAG acceptors were identified in the upstream region of
## the fourth and fifth exons located in TCONS_00010012.
## Extract the sequences for transcript TCONS_00010012:
library(BSgenome.Hsapiens.UCSC.hg19)
genome <- BSgenome.Hsapiens.UCSC.hg19
exons_seq <- getSeq(genome, exons[[1]])

## TCONS_00010012 has 4 exons:
exons_seq

## The most common triplet among the lincRNA sequences was CAG. Identify
## the location of this pattern in all exons.
cag_loc <- vmatchPattern("CAG", exons_seq)

## Convert the first occurance of CAG in each exon back to genome
## coordinates.
first_loc <- do.call(c, sapply(cag_loc, "[", 1, simplify=TRUE))
pmapFromTranscripts(first_loc, exons[[1]])

## ----------------------------------------------------------------------
## C. Map dbSNP variants to CDS or cDNA coordinates
## ----------------------------------------------------------------------
```

```
## The GIPR gene encodes a G-protein coupled receptor for gastric
## inhibitory polypeptide (GIP). Originally GIP was identified to
## inhibited gastric acid secretion and gastrin release but was later
## demonstrated to stimulate insulin release in the presence of elevated
## glucose.

## In this example 5 SNPs located in the GIPR gene are mapped to cDNA
## coordinates. A list of SNPs in GIPR can be downloaded from dbSNP or
## NCBI.
rsids <- c("rs4803846", "rs139322374", "rs7250736", "rs7250754",
           "rs9749185")

## Extract genomic coordinates with a SNPlocs package.
library(SNPlocs.Hsapiens.dbSNP144.GRCh38)
snps <- snpsById(SNPlocs.Hsapiens.dbSNP144.GRCh38, rsids)

## Gene regions of GIPR can be extracted from a TxDb package of
## compatible build. The TxDb package uses Entrez gene identifiers
## and GIPR is a gene symbol. Let's first lookup its Entrez gene ID.
library(org.Hs.eg.db)
GIPR_geneid <- get("GIPR", org.Hs.egSYMBOL2EG)

## The transcriptsBy() extractor returns a range for each transcript that
## includes the UTR and exon regions (i.e., cDNA).
library(TxDb.Hsapiens.UCSC.hg38.knownGene)
txdb <- TxDb.Hsapiens.UCSC.hg38.knownGene
tx_by_gene <- transcriptsBy(txdb, "gene")
GIPR_transcripts <- tx_by_gene[GIPR_geneid]
GIPR_transcripts  # all 8 GIPR transcripts are on chr19, positive strand

## Before mapping, the chromosome names (seqlevels) in the two
## objects must be harmonized. The style is NCBI for 'snps' and
## UCSC for 'GIPR_transcripts'.
seqlevelsStyle(snps)
seqlevelsStyle(GIPR_transcripts)

## Modify the style (and genome) in 'snps' to match 'GIPR_transcripts'.
seqlevelsStyle(snps) <- seqlevelsStyle(GIPR_transcripts)

## The 'GIPR_transcripts' object is a GRangesList of length 1. This single
## list element contains the cDNA range for 8 different transcripts. To
## map to each transcript individually 'GIPR_transcripts' must be unlisted
## before mapping.

## Map all 5 SNPS to all 8 transcripts:
mapToTranscripts(snps, unlist(GIPR_transcripts))

## Map the first SNP to transcript "ENST00000590918.5" and the second to
## "ENST00000263281.7".
pmapToTranscripts(snps[1:2], unlist(GIPR_transcripts)[1:2])

## The cdsBy() extractor returns CDS parts by gene or by transcript.
## Extract the CDS parts for transcript "ENST00000263281.7".
cds <- cdsBy(txdb, "tx", use.names=TRUE)["ENST00000263281.7"]
cds

## The 'cds' object is a GRangesList of length 1 containing the ranges of
```

```
## all CDS parts for single transcript "ENST00000263281.7".

## To map to the concatenated group of ranges leave 'cds' as a GRangesList.
mapToTranscripts(snps, cds)

## Only the second SNP could be mapped. Unlisting the 'cds' object maps
## the SNPs to the individual cds ranges (vs the concatenated range).
mapToTranscripts(snps[2], unlist(cds))

## The location is the same because the SNP hit the first CDS part. If
## the transcript were on the "-" strand the difference in concatenated
## vs non-concatenated position would be more obvious.

## Change strand:
strand(cds) <- strand(snps) <- "-"
mapToTranscripts(snps[2], unlist(cds))
}
```

---

microRNAs   *Extract microRNA or tRNA genomic ranges from an object*

Description

Generic functions to extract microRNA or tRNA genomic ranges from an object. This page documents the methods for TxDb objects only.

Usage

```
microRNAs(x)
## S4 method for signature 'TxDb'
microRNAs(x)

tRNAs(x)
## S4 method for signature 'TxDb'
tRNAs(x)
```

Arguments

x   A TxDb object.

Value

A GRanges object.

Author(s)

M. Carlson

See Also

- transcripts, transcriptsBy, and transcriptsByOverlaps for the core genomic features extractors.
- The TxDb class.

Examples

```
## Not run: library(TxDb.Hsapiens.UCSC.hg19.knownGene)
library(mirbase.db)
microRNAs(TxDb.Hsapiens.UCSC.hg19.knownGene)

## End(Not run)
```

---

nearest-methods   *Finding the nearest genomic range neighbor in a TxDb*

Description

The `distance` methods for TxDb objects and subclasses.

Usage

```
## S4 method for signature 'GenomicRanges,TxDb'
distance(x, y, ignore.strand=FALSE,
    ..., id, type=c("gene", "tx", "exon", "cds"))
```

Arguments

x	The query [GenomicRanges](#) instance.
y	For `distance`, a [TxDb](#) instance. The id is used to extract ranges from the [TxDb](#) which are then used to compute the distance from x.
id	A `character` vector the same length as x. The id must be identifiers in the [TxDb](#) object. type indicates what type of identifier id is.
type	A `character(1)` describing the id. Must be one of 'gene', 'tx', 'exon' or 'cds'.
ignore.strand	A `logical` indicating if the strand of the ranges should be ignored. When `TRUE`, strand is set to '+'.
...	Additional arguments for methods.

Details

- distance: Returns the distance for each range in x to the range extracted from the [TxDb](#) object y. Values in id are matched to one of 'gene_id', 'tx_id', 'exon_id' or 'cds_id' identifiers in the [TxDb](#) and the corresponding ranges are extracted. The type argument specifies which identifier is represented in id. The extracted ranges are used in the distance calculation with the ranges in x.

  The method returns NA values when the genomic region defined by id cannot be collapsed into a single range (e.g., when a gene spans multiple chromosomes) or if the id is not found in y.

  The behavior of `distance` with respect to zero-width ranges has changed in Bioconductor 2.12. See the man page ?distance in IRanges for details.

Value

For `distance`, an integer vector of distances between the ranges in x and y.

Author(s)

Valerie Obenchain <vobencha@fhcrc.org>

See Also

- nearest-methods man page in IRanges.

- nearest-methods man page in GenomicRanges.

Examples

```
## ---------------------------------------------------------
## distance()
## ---------------------------------------------------------

library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
gr <- GRanges(c("chr2L", "chr2R"),
              IRanges(c(100000, 200000),  width=100))
distance(gr, txdb, id=c("FBgn0259717", "FBgn0261501"), type="gene")
distance(gr, txdb, id=c("10000", "23000"), type="cds")

## The id's must be in the appropriate order with respect to 'x'.
distance(gr, txdb, id=c("4", "4097"), type="tx")

## 'id' "4" is on chr2L and "4097" is on chr2R.
transcripts(txdb, filter=list(tx_id=c("4", "4097")))

## If we reverse the 'id' the chromosomes are incompatable with gr.
distance(gr, txdb, id=c("4097", "4"), type="tx")

## distance() compares each 'x' to the corresponding 'y'.
## If an 'id' is not found in the TxDb 'y' will not
## be the same lenth as 'x' and an error is thrown.
## Not run:
distance(gr, txdb, id=c("FBgn0000008", "INVALID"), type="gene") ## will fail

## End(Not run)
```

---

proteinToGenome	*Map protein-relative coordinates to genomic coordinates*

Description

proteinToGenome is a generic function for mapping ranges of protein-relative positions to the genome.

NOTE: This man page is for the proteinToGenome S4 generic function and methods defined in the **GenomicFeatures** package, which are (loosely) modeled on the proteinToGenome function from the **ensembldb** package. See ?ensembldb::proteinToGenome for the latter.

Usage

```
## S4 generic function:
proteinToGenome(x, db, ...)  # dispatch is on 2nd argument 'db'

## S4 method for signature 'ANY'
proteinToGenome(x, db)

## S4 method for signature 'GRangesList'
proteinToGenome(x, db)
```

Arguments

x
A named IRanges object (or derivative) containing ranges of *protein-relative positions* (protein-relative positions are positions relative to a protein sequence). The names on x must be transcript names present in db. More precisely, for the default proteinToGenome() method, names(x) must be a subset of:

```
mcols(transcripts(db, columns="tx_name"))$tx_name
```

And for the method for GRangesList objects, names(x) must be a subset of:

```
names(db)
```

db
For the default proteinToGenome() method: A TxDb object or any object that supports transcripts() and cdsBy() (e.g. an EnsDb object from the **ensembldb** package).

For the method for GRangesList objects: A named GRangesList object (or derivative) where each list element is a GRanges object representing a CDS (the ranges in the GRanges object must represent the CDS parts ordered by ascending exon rank).

...
Further arguments to be passed to specific methods.

Details

The proteinToGenome() method for GRangesList objects is the workhorse behind the default method. Note that the latter is a thin wrapper around the former, which simply does the following:

1. Use cdsBy() to extract the CDS parts from db. The CDS parts are returned in a GRangesList object that has the names of the transcript on it (one transcript name per list element).

2. Call proteinToGenome() on x and the GRangesList object returned by cdsBy().

Value

A named GRangesList object *parallel* to x (the transcript names on x are propagated). The i-th list element in the returned object is the result of mapping the range of protein-relative positions x[i] to the genome.

Note that a given range in x can only be mapped to the genome if the name on it is the name of a *coding* transcript. If it's not (i.e. if it's the name of a *non-coding* transcript), then an empty GRanges object is placed in the returned object to indicate the impossible mapping, and a warning is issued.

Otherwise, if a given range in x can be mapped to the genome, then the result of the mapping is represented by a non-empty GRanges object. Note that this object represents the original CDS

associated to x, trimmed on its 5' end or 3' end, or on both. Furthermore, this object will have the same metadata columns as the GRanges object representing the original CDS, plus the 2 following ones:

- protein_start: The protein-relative start of the mapping.
- protein_end: The protein-relative end of the mapping.

Note

Unlike ensembldb::proteinToGenome() which can work either with Ensembl protein IDs or Ensembl transcript IDs on x, the default proteinToGenome() method described above only accepts *transcript names* on x.

This means that, if the user is in possession of protein IDs, they must first replace them with the corresponding transcript IDs (referred to as *transcript names* in the context of TxDb objects). How to do this exactly depends on the origin of those IDs (UCSC, Ensembl, GTF/GFF3 file, FlyBase, etc...)

Author(s)

H. Pagès, using ensembldb::proteinToGenome() for inspiration and design.

Examples

```
## ---------------------------------------------------------------------
## USING TOY CDS
## ---------------------------------------------------------------------

## CDS1 has 2 CDS parts:
CDS1 <- GRanges(c("chrX:11-60:+", "chrX:101-125:+"))

## CDS2 has 3 CDS parts:
CDS2 <- GRanges(c("chrY:201-230:-", "chrY:101-125:-", "chrY:11-60:-"))

## Put them in a GRangesList object:
cds_by_tx <- GRangesList(TX1=CDS1, TX2=CDS2)
cds_by_tx

x1 <- IRanges(start=8, end=20, names="TX1")
proteinToGenome(x1, cds_by_tx)

x2 <- IRanges(start=c(1, 18), end=c(25, 20), names=c("TX1", "TX1"))
x2
```

```
proteinToGenome(x2, cds_by_tx)

x3 <- IRanges(start=8, end=15, names="TX2")
proteinToGenome(x3, cds_by_tx)

x4 <- c(x3, x2)
x4
proteinToGenome(x4, cds_by_tx)

## ---------------------------------------------------------------------
## USING A TxDb OBJECT
## ---------------------------------------------------------------------
library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene

## The first transcript (FBtr0309810) is non-coding:
x <- IRanges(c(FBtr0309810="11-55", FBtr0306539="90-300"))
res <- proteinToGenome(x, txdb)
res
```

---

select-methods   *Using the "select" interface on TxDb objects*

Description

select, columns and keys can be used together to extract data from a TxDb object.

Details

In the code snippets below, x is a TxDb object.

keytypes(x): allows the user to discover which keytypes can be passed in to select or keys and the keytype argument.

keys(x, keytype, pattern, column, fuzzy): Return keys for the database contained in the TxDb object .

The keytype argument specifies the kind of keys that will be returned. By default keys will return the "GENEID" keys for the database.

If keys is used with pattern, it will pattern match on the keytype.

But if the column argument is also provided along with the pattern argument, then pattern will be matched against the values in column instead.

And if keys is called with column and no pattern argument, then it will return all keys that have corresponding values in the column argument.

Thus, the behavior of keys all depends on how many arguments are specified.

Use of the fuzzy argument will toggle fuzzy matching to TRUE or FALSE. If pattern is not used, fuzzy is ignored.

columns(x): Show which kinds of data can be returned for the TxDb object.

select(x, keys, columns, keytype): When all the appropriate arguments are specified select will retrieve the matching data as a data.frame based on parameters for selected keys and columns and keytype arguments.

Examples

```
txdb_file <- system.file("extdata", "Biomart_Ensembl_sample.sqlite",
                          package="GenomicFeatures")
txdb <- loadDb(txdb_file)
txdb

## find key types
keytypes(txdb)

## list IDs that can be used to filter
head(keys(txdb, "GENEID"))
head(keys(txdb, "TXID"))
head(keys(txdb, "TXNAME"))

## list columns that can be returned by select
columns(txdb)

## call select
res <- select(txdb, head(keys(txdb, "GENEID")),
              columns=c("GENEID","TXNAME"),
              keytype="GENEID")
head(res)
```

---

transcriptLengths   *Extract the transcript lengths (and other metrics) from a TxDb object*

Description

The transcriptLengths function extracts the transcript lengths from a [TxDb](#) object. It also returns the CDS and UTR lengths for each transcript if the user requested them.

Usage

```
transcriptLengths(txdb, with.cds_len=FALSE,
                  with.utr5_len=FALSE, with.utr3_len=FALSE, ...)
```

Arguments

txdb   A [TxDb](#) object.

with.cds_len, with.utr5_len, with.utr3_len

                TRUE or FALSE. Whether or not to also extract and return the CDS, 5' UTR, and
                3' UTR lengths for each transcript.

...   Additional arguments used by transcripts and other accessor functions.

Details

All the lengths are counted in number of nucleotides.

The length of a processed transcript is just the sum of the lengths of its exons. This should not be confounded with the length of the stretch of DNA transcribed into RNA (a.k.a. transcription unit), which can be obtained with `width(transcripts(txdb))`.

Value

A data frame with 1 row per transcript. The rows are guaranteed to be in the same order as the elements of the GRanges object returned by `transcripts`(txdb). The data frame has between 5 and 8 columns, depending on what the user requested via the `with.cds_len`, `with.utr5_len`, and `with.utr3_len` arguments.

The first 3 columns are the same as the metadata columns of the object returned by

```
transcripts(txdb, columns=c("tx_id", "tx_name", "gene_id"))
```

that is:

- `tx_id`: The internal transcript ID. This ID is unique within the scope of the TxDb object. It is not an official or public ID (like an Ensembl or FlyBase ID) or an Accession number, so it cannot be used to lookup the transcript in public data bases or in other TxDb objects. Furthermore, this ID could change when re-running the code that was used to make the TxDb object.

- `tx_name`: An official/public transcript name or ID that can be used to lookup the transcript in public data bases or in other TxDb objects. This column is not guaranteed to contain unique values and it can contain NAs.

- `gene_id`: The official/public ID of the gene that the transcript belongs to. Can be NA if the gene is unknown or if the transcript is not considered to belong to a gene.

The other columns are quantitative:

- `nexon`: The number of exons in the transcript.
- `tx_len`: The length of the processed transcript.
- `cds_len`: [optional] The length of the CDS region of the processed transcript.
- `utr5_len`: [optional] The length of the 5' UTR region of the processed transcript.
- `utr3_len`: [optional] The length of the 3' UTR region of the processed transcript.

- The TxDb class.

Examples

```
library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
dm3_txlens <- transcriptLengths(txdb)
head(dm3_txlens)

dm3_txlens <- transcriptLengths(txdb, with.cds_len=TRUE,
                                      with.utr5_len=TRUE,
                                      with.utr3_len=TRUE)
head(dm3_txlens)

## When cds_len is 0 (non-coding transcript), utr5_len and utr3_len
## must also be 0:
non_coding <- dm3_txlens[dm3_txlens$cds_len == 0, ]
stopifnot(all(non_coding[6:8] == 0))

## When cds_len is not 0 (coding transcript), cds_len + utr5_len +
## utr3_len must be equal to tx_len:
coding <- dm3_txlens[dm3_txlens$cds_len != 0, ]
stopifnot(all(rowSums(coding[6:8]) == coding[[5]]))

## A sanity check:
stopifnot(identical(dm3_txlens$tx_id, mcols(transcripts(txdb))$tx_id))
```

---

transcriptLocs2refLocs

Converting transcript-based locations into reference-based locations

---

Description

transcriptLocs2refLocs converts transcript-based locations into reference-based (aka chromosome-based or genomic) locations.

transcriptWidths computes the lengths of the transcripts (called the "widths" in this context) based on the boundaries of their exons.

Usage

```
transcriptLocs2refLocs(tlocs,
        exonStarts=list(), exonEnds=list(), strand=character(0),
        decreasing.rank.on.minus.strand=FALSE, error.if.out.of.bounds=TRUE)

transcriptWidths(exonStarts=list(), exonEnds=list())
```

Arguments

tlocs   A list of integer vectors of the same length as exonStarts and exonEnds. Each element in tlocs must contain transcript-based locations.

exonStarts, exonEnds

        The starts and ends of the exons, respectively.

        Each argument can be a list of integer vectors, an [IntegerList](#) object, or a character vector where each element is a comma-separated list of integers. In addition, the lists represented by exonStarts and exonEnds must have the same shape i.e. have the same lengths and have elements of the same lengths. The length of exonStarts and exonEnds is the number of transcripts.

strand   A character vector of the same length as exonStarts and exonEnds specifying the strand ("+" or "-") from which the transcript is coming.

decreasing.rank.on.minus.strand

        TRUE or FALSE. Describes the order of exons in transcripts located on the minus strand: are they ordered by increasing (default) or decreasing rank?

error.if.out.of.bounds

        TRUE or FALSE. Controls how out of bound tlocs are handled: an error is thrown (default) or NA is returned.

Value

For transcriptLocs2refLocs: A list of integer vectors of the same shape as tlocs.

For transcriptWidths: An integer vector with one element per transcript.

transcripts   *Extract genomic features from a TxDb-like object*

Description

Generic functions to extract genomic features from a TxDb-like object. This page documents the methods for TxDb objects only.

Usage

```
transcripts(x, ...)
## S4 method for signature 'TxDb'
transcripts(x, columns=c("tx_id", "tx_name"), filter=NULL, use.names=FALSE)

exons(x, ...)
## S4 method for signature 'TxDb'
exons(x, columns="exon_id", filter=NULL, use.names=FALSE)

cds(x, ...)
## S4 method for signature 'TxDb'
cds(x, columns="cds_id", filter=NULL, use.names=FALSE)

genes(x, ...)
## S4 method for signature 'TxDb'
genes(x, columns="gene_id", filter=NULL, single.strand.genes.only=TRUE)

## S4 method for signature 'TxDb'
promoters(x, upstream=2000, downstream=200, use.names=TRUE, ...)
## S4 method for signature 'TxDb'
terminators(x, upstream=2000, downstream=200, use.names=TRUE, ...)
```

Arguments

x	A TxDb object.
...	For the `transcripts()`, `exons()`, `cds()`, and `genes()` generic functions: arguments to be passed to methods.
	For the `promoters()` and `terminators()` methods for TxDb objects: arguments to be passed to the internal call to `transcripts()`.
columns	Columns to include in the output. Must be NULL or a character vector as given by the columns method. With the following restrictions:

- "TXCHROM" and "TXSTRAND" are not allowed for `transcripts()`.
- "EXONCHROM" and "EXONSTRAND" are not allowed for `exons()`.
- "CDSCHROM" and "CDSSTRAND" are not allowed for `cds()`.

	If the vector is named, those names are used for the corresponding column in the element metadata of the returned object.
filter	Either NULL or a named list of vectors to be used to restrict the output. Valid names for this list are: "gene_id", "tx_id", "tx_name", "tx_chrom", "tx_strand", "exon_id", "exon_name", "exon_chrom", "exon_strand", "cds_id", "cds_name", "cds_chrom", "cds_strand" and "exon_rank".
use.names	TRUE or FALSE. If TRUE, the feature names are set as the names of the returned object, with NAs being replaced with empty strings.
single.strand.genes.only	
	TRUE or FALSE. If TRUE (the default), then genes are returned in a GRanges object and those genes that cannot be represented by a single genomic range (because

they have exons located on both strands of the same reference sequence or on more than one reference sequence) are dropped with a message.

If FALSE, then all the genes are returned in a GRangesList object with the columns specified thru the columns argument set as *top level* metadata columns. (Please keep in mind that the *top level* metadata columns of a GRangesList object are not displayed by the show() method.)

upstream, downstream

For promoters(): Single integer values indicating the number of bases upstream and downstream from the TSS (transcription start sites).

For terminators(): Single integer values indicating the number of bases upstream and downstream from the TES (transcription end sites).

For additional details see ?GenomicRanges::promoters in the **GenomicRanges** package.

Details

These are the main functions for extracting features from a TxDb-like object. Note that cds() extracts the bulk *CDS parts* stored in x, that is, the CDS regions associated with exons. It is often more useful to extract them grouped by transcript with cdsBy().

To restrict the output based on interval information, use the transcriptsByOverlaps(), exonsByOverlaps(), or cdsByOverlaps() function.

The promoters() and terminators() functions compute user-defined promoter or terminator regions for the transcripts in a TxDb-like object. The returned object is a GRanges with one range per transcript in the TxDb-like object. Each range represents the promoter or terminator region associated with a transcript, that is, the region around the TSS (transcription start site) or TES (transcription end site) the span of which is defined by upstream and downstream.

For additional details on how the promoter and terminator ranges are computed and the handling of + and – strands see ?GenomicRanges::promoters in the **GenomicRanges** package.

Value

A GRanges object. The only exception being when genes() is used with single.strand.genes.only=FALSE, in which case a GRangesList object is returned.

Examples

```
txdb_file <- system.file("extdata", "hg19_knownGene_sample.sqlite",
                         package="GenomicFeatures")
txdb <- loadDb(txdb_file)

## ---------------------------------------------------------------------
## transcripts()
## ---------------------------------------------------------------------

tx1 <- transcripts(txdb)
tx1

transcripts(txdb, use.names=TRUE)
transcripts(txdb, columns=NULL, use.names=TRUE)

filter <- list(tx_chrom = c("chr3", "chr5"), tx_strand = "+")
tx2 <- transcripts(txdb, filter=filter)
tx2

## Sanity checks:
stopifnot(
  identical(mcols(tx1)$tx_id, seq_along(tx1)),
  identical(tx2, tx1[seqnames(tx1) == "chr3" & strand(tx1) == "+"])
)

## ---------------------------------------------------------------------
## exons()
## ---------------------------------------------------------------------

exons(txdb, columns=c("EXONID", "TXNAME"),
            filter=list(exon_id=1))
exons(txdb, columns=c("EXONID", "TXNAME"),
            filter=list(tx_name="uc009vip.1"))

## ---------------------------------------------------------------------
## genes()
## ---------------------------------------------------------------------

genes(txdb)  # a GRanges object
cols <- c("tx_id", "tx_chrom", "tx_strand",
          "exon_id", "exon_chrom", "exon_strand")
## By default, genes are returned in a GRanges object and those that
## cannot be represented by a single genomic range (because they have
## exons located on both strands of the same reference sequence or on
## more than one reference sequence) are dropped with a message:
single_strand_genes <- genes(txdb, columns=cols)
```

```
## Because we've returned single strand genes only, the "tx_chrom"
## and "exon_chrom" metadata columns are guaranteed to match
## 'seqnames(single_strand_genes)':
stopifnot(identical(as.character(seqnames(single_strand_genes)),
                    as.character(mcols(single_strand_genes)$tx_chrom)))
stopifnot(identical(as.character(seqnames(single_strand_genes)),
                    as.character(mcols(single_strand_genes)$exon_chrom)))

## and also the "tx_strand" and "exon_strand" metadata columns are
## guaranteed to match 'strand(single_strand_genes)':
stopifnot(identical(as.character(strand(single_strand_genes)),
                    as.character(mcols(single_strand_genes)$tx_strand)))
stopifnot(identical(as.character(strand(single_strand_genes)),
                    as.character(mcols(single_strand_genes)$exon_strand)))

all_genes <- genes(txdb, columns=cols, single.strand.genes.only=FALSE)
all_genes  # a GRangesList object
multiple_strand_genes <- all_genes[elementNROWS(all_genes) >= 2]
multiple_strand_genes
mcols(multiple_strand_genes)

## -------------------------------------------------------------------
## promoters() and terminators()
## -------------------------------------------------------------------

## This:
promoters(txdb, upstream=100, downstream=50)
## is equivalent to:
tx <- transcripts(txdb, use.names=TRUE)
promoters(tx, upstream=100, downstream=50)

## And this:
terminators(txdb, upstream=100, downstream=50)
## is equivalent to:
terminators(tx, upstream=100, downstream=50)

## Extra arguments are passed to transcripts(). So this:
columns <- c("tx_name", "gene_id")
promoters(txdb, upstream=100, downstream=50, columns=columns)
## is equivalent to:
promoters(transcripts(txdb, columns=columns, use.names=TRUE),
          upstream=100, downstream=50)
```

---

transcriptsBy   *Extract and group genomic features of a given type from a TxDb-like*
                               object

Description

Generic functions to extract genomic features of a given type grouped based on another type of
genomic feature. This page documents the methods for TxDb objects only.

Usage

```
transcriptsBy(x, by=c("gene", "exon", "cds"), ...)
## S4 method for signature 'TxDb'
transcriptsBy(x, by=c("gene", "exon", "cds"), use.names=FALSE)

exonsBy(x, by=c("tx", "gene"), ...)
## S4 method for signature 'TxDb'
exonsBy(x, by=c("tx", "gene"), use.names=FALSE)

cdsBy(x, by=c("tx", "gene"), ...)
## S4 method for signature 'TxDb'
cdsBy(x, by=c("tx", "gene"), use.names=FALSE)

intronsByTranscript(x, ...)
## S4 method for signature 'TxDb'
intronsByTranscript(x, use.names=FALSE)

fiveUTRsByTranscript(x, ...)
## S4 method for signature 'TxDb'
fiveUTRsByTranscript(x, use.names=FALSE)

threeUTRsByTranscript(x, ...)
## S4 method for signature 'TxDb'
threeUTRsByTranscript(x, use.names=FALSE)
```

Arguments

x	A TxDb object.
...	Arguments to be passed to or from methods.
by	One of "gene", "exon", "cds" or "tx". Determines the grouping.
use.names	Controls how to set the names of the returned GRangesList object. These functions return all the features of a given type (e.g. all the exons) grouped by another feature type (e.g. grouped by transcript) in a GRangesList object. By default (i.e. if use.names is FALSE), the names of this GRangesList object (aka the group names) are the internal ids of the features used for grouping (aka the grouping features), which are guaranteed to be unique. If use.names is TRUE, then the names of the grouping features are used instead of their internal ids. For example, when grouping by transcript (by="tx"), the default group names are the transcript internal ids ("tx_id"). But, if use.names=TRUE, the group names are the transcript names ("tx_name"). Note that, unlike the feature ids, the feature names are not guaranteed to be unique or even defined (they could be all NAs). A warning is issued when this happens. See ?id2name for more information about feature internal ids and feature external names and how to map the formers to the latters.
	Finally, use.names=TRUE cannot be used when grouping by gene by="gene". This is because, unlike for the other features, the gene ids are external ids (e.g. Entrez Gene or Ensembl ids) so the db doesn't have a "gene_name" column for storing alternate gene names.

Details

These functions return a GRangesList object where the ranges within each of the elements are ordered according to the following rule:

When using exonsBy or cdsBy with by="tx", the returned exons or CDS parts are ordered by ascending rank for each transcript, that is, by their position in the transcript. In all other cases, the ranges will be ordered by chromosome, strand, start, and end values.

Value

A GRangesList object.

transcriptsByOverlaps *Extract genomic features from a TxDb-like object based on their ge-
                        nomic location*

Description

Generic functions to extract genomic features for specified genomic locations. This page documents
the methods for TxDb objects only.

Usage

```
transcriptsByOverlaps(x, ranges,
                      maxgap = -1L, minoverlap = 0L,
                      type = c("any", "start", "end"), ...)
## S4 method for signature 'TxDb'
transcriptsByOverlaps(x, ranges,
                      maxgap = -1L, minoverlap = 0L,
                      type = c("any", "start", "end"),
                      columns = c("tx_id", "tx_name"))

exonsByOverlaps(x, ranges,
                maxgap = -1L, minoverlap = 0L,
                type = c("any", "start", "end"), ...)
## S4 method for signature 'TxDb'
exonsByOverlaps(x, ranges,
                maxgap = -1L, minoverlap = 0L,
                type = c("any", "start", "end"),
                columns = "exon_id")

cdsByOverlaps(x, ranges,
              maxgap = -1L, minoverlap = 0L,
              type = c("any", "start", "end"), ...)
## S4 method for signature 'TxDb'
cdsByOverlaps(x, ranges,
              maxgap = -1L, minoverlap = 0L,
              type = c("any", "start", "end"),
              columns = "cds_id")
```

Arguments

x   A TxDb object.

ranges   A GRanges object to restrict the output.

maxgap, minoverlap, type

> Used in the internal call to findOverlaps() to detect overlaps. See ?findOverlaps
> in the **IRanges** package for a description of these arguments.

...   Arguments to be passed to or from methods.

columns   Columns to include in the output. See ?transcripts for the possible values.

Details

These functions subset the results of transcripts, exons, and cds function calls with using the
results of findOverlaps calls based on the specified ranges.

Value

a GRanges object

P. Aboyoun

See Also

- transcripts and transcriptsBy for more ways to extract genomic features from a TxDb-
  like object.

- transcriptLengths for extracting the transcript lengths (and other metrics) from a TxDb
  object.

- exonicParts and intronicParts for extracting non-overlapping exonic or intronic parts
  from a TxDb-like object.

- extractTranscriptSeqs for extracting transcript (or CDS) sequences from chromosome se-
  quences.

- coverageByTranscript for computing coverage by transcript (or CDS) of a set of ranges.

- select-methods for how to use the simple "select" interface to extract information from a TxDb
  object.

- id2name for mapping TxDb internal ids to external names for a given feature type.

- The TxDb class.

Examples

```
txdb <- loadDb(system.file("extdata", "hg19_knownGene_sample.sqlite",
                           package="GenomicFeatures"))
gr <- GRanges(Rle("chr1", 2),
              IRanges(c(500,10500), c(10000,30000)),
              strand = Rle("-", 2))
transcriptsByOverlaps(txdb, gr)
```

```
TxDb-class                    TxDb objects
```

Description

The TxDb class is a container for storing transcript annotations.

Methods

In the code snippets below, x is a TxDb object.

metadata(x): Return x's metadata in a data frame.

seqlevels0(x): Get the *sequence levels* originally in x. This ignores any change the user might have made to the *sequence levels* with the seqlevels setter.

seqlevels(x), seqlevels(x) <- value: Get or set the *sequence levels* in x.

seqinfo(x), seqinfo(x) <- value: Get or set the information about the underlying sequences. Note that, for now, the setter only supports replacement of the sequence names, i.e., except for their sequence names (accessed with seqnames(value) and seqnames(seqinfo(x)), respectively), Seqinfo objects value (supplied) and seqinfo(x) (current) must be identical.

isActiveSeq(x): Return the currently active sequences for this txdb object as a named logical vector. Only active sequences will be tapped when using the supplied accessor methods. Inactive sequences will be ignored. By default, all available sequences will be active.

isActiveSeq(x) <- value: Allows the user to change which sequences will be actively accessed by the accessor methods by altering the contents of this named logical vector.

seqlevelsStyle(x), seqlevelsStyle(x) <- value: Get or set the seqname style for x. See the seqlevelsStyle generic getter and setter in the **GenomeInfoDb** package for more information.

as.list(x): Dump the entire db into a list of data frames, say txdb_dump, that can then be used to recreate the original db with do.call(makeTxDb, txdb_dump) with no loss of information (except possibly for some of the metadata). Note that the transcripts are dumped in the same order in all the data frames.

See Also

- makeTxDbFromUCSC, makeTxDbFromBiomart, and makeTxDbFromEnsembl, for making a TxDb object from online resources.
- makeTxDbFromGRanges and makeTxDbFromGFF for making a TxDb object from a GRanges object, or from a GFF or GTF file.
- saveDb and loadDb in the **AnnotationDbi** package for saving and loading a TxDb object as an SQLite file.
- transcripts, transcriptsBy, and transcriptsByOverlaps, for extracting genomic feature locations from a TxDb-like object.
- transcriptLengths for extracting the transcript lengths (and other metrics) from a TxDb object.
- select-methods for how to use the simple "select" interface to extract information from a TxDb object.
- The Seqinfo class in the **GenomeInfoDb** package.

Examples

```
txdb_file <- system.file("extdata", "Biomart_Ensembl_sample.sqlite",
                         package="GenomicFeatures")
txdb <- loadDb(txdb_file)
txdb

## Use of seqinfo():
seqlevelsStyle(txdb)
seqinfo(txdb)
seqlevels(txdb)
seqlengths(txdb)  # shortcut for 'seqlengths(seqinfo(txdb))'
isCircular(txdb)  # shortcut for 'isCircular(seqinfo(txdb))'
names(which(isCircular(txdb)))

## You can set user-supplied seqlevels on 'txdb' to restrict any further
## operations to a subset of chromosomes:
seqlevels(txdb) <- c("Y", "6")
## Then you can restore the seqlevels stored in the db:
seqlevels(txdb) <- seqlevels0(txdb)

## Use of as.list():
txdb_dump <- as.list(txdb)
txdb_dump
txdb1 <- do.call(makeTxDb, txdb_dump)
stopifnot(identical(as.list(txdb1), txdb_dump))
```
